The NASA STI Program...in Profile

Since its founding, NASA has been dedicated to ensuring U.S. leadership in aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays an important part in helping NASA maintain its leadership role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

A number of specialized services help round out the Program's diverse offerings, including creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to NASA Access Help Desk at (301) 621-0134
- Send us your question via the **Internet** to help@sti.nasa.gov
- **Write to:**

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the International Aerospace Database, managed by the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

Front Matter
A typical citation and abstract sample explaining the standard format, which includes codes for ordering reports.

An Abstract Section
Citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.

An Index Section
- Subject
- Personal author
- Corporate source
- Contract number
- Report number.

Appendix
A guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors companion journals, *International Aerospace Abstracts (IAA)*, and *NASA Open Volumes on Aerospace (NOVA)*. They list abstracts of the open literature on aerospace subjects available worldwide. IAA is available from the American Institute of Aeronautics and Astronautics (AIAA), and *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Reports found in *STAR* are also available through the NASA online retrieval service, RECON, and the Aerospace Database through DIALOG.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **2573**

02 AERODYNAMICS **2574**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **2582**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **2584**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **2586**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **2591**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **2592**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **2595**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **2597**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **2598**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **2599**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **2608**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **2609**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **2610**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING . **2614**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—no abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **2614**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **2620**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **2621**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **2633**

24 COMPOSITE MATERIALS **2634**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **2642**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **2649**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **2653**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **2659**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **2663**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology.*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **2665**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **2671**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **2687**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **2694**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **2708**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **2711**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **2716**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **2721**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **2723**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **2732**

43 EARTH RESOURCES AND REMOTE SENSING **2737**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **2758**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **2760**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **2769**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **2777**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **2788**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **2792**

52 AEROSPACE MEDICINE **2794**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **2796**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **2799**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY **2803**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **2803**

60 COMPUTER OPERATIONS AND HARDWARE **2805**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **2808**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **2815**
Includes computer networks and special application computer systems.

63 CYBERNETICS **2817**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **2827**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **2830**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **2831**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS ..... **N.A.**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **2831**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography;* for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics,* or *92 Solar Physics.*

71 ACOUSTICS **2844**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **2846**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **2851**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **2852**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **2857**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **2862**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **2871**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **2872**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **2872**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **2873**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **2886**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY **2886**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **2887**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) **2887**

89 ASTRONOMY **2888**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **2891**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **2896**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **2898**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see *93 Space Radiation.*

93 SPACE RADIATION **2899**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The first part of the proposed research was a joint effort between our group and the Applied Physics Laboratory (APL), University of Washington. Our own research goal is to investigate the relation between the air-sea exchange processes and the sea state over the open ocean and to compare these findings with our previous results obtained over a small body of water namely, Lake Washington. The goals of the APL researchers are to study (1) the infrared sea surface temperature (SST) signature of breaking waves and surface slicks, and (2) microwave and acoustic scattering from water surface. The task of our group in this joint effort is to conduct measurements of surface fluxes (of momentum, sensible heat, and water vapor) and atmospheric radiation (longwave and shortwave) to achieve our research goal as well as to provide crucial complementary data for the APL studies. The progress of the project is summarized. Author

Avail: CASI HC A06/MF A02

The performance of an axial-flow fan-compressor unit is basically unsteady when there is ingestion of water along with the gas phase. The gas phase is a mixture of air and water vapor in the case of a bypass fan engine that provides thrust power to an aircraft. The liquid water may be in the form of droplets and film at entry to the fan. The unsteadiness is then associated with the relative motion between the gas phase and water, at entry and within the machine, while the water undergoes impact on material surfaces, centrifuging, heat and mass transfer processes, and reingestion in blade wakes, following peal off from blade surfaces. The unsteadiness may be caused by changes in atmospheric conditions and at entry into and exit from rain storms while the aircraft is in flight. In a multi-stage machine, with an uneven distribution of blade tip clearance, the combined effect of various processes in the presence of steady or time-dependent ingestion is such as to make the performance of a fan and a compressor unit time-dependent from the start of ingestion up to a short time following termination of ingestion. The original WINCOF code was developed without accounting for the relative motion between gas and liquid phases in the ingested fluid. A modification of the WINCOF code was developed and named WINCOF-1. The WINCOF-1 code can provide the transient performance of a fan-compressor unit under a variety of input conditions. FEASIBILITY STUDY OF A LONG DURATION BALLOON FLIGHT WITH NASA/GSFC AND SOVIET SPACE AGENCY GAMMA RAY SPECTROMETERS
William E. Sharp and Glenn Knoll 18 Dec. 1989 23 p
(Grant NAG5-1158)
(NASA-CR-192934; NAS 1.26:192934) Avail: CASI HC A03/MF A01

A feasibility study of conducting a joint NASA/GSFC and Soviet Space Agency long duration balloon flight at the Antarctic in Jan. 1993 is reported. The objective of the mission is the verification and calibration of gamma ray and neutron remote sensing instruments which can be used to obtain geochemical maps of the surface of planetary bodies. The gamma ray instruments in question are the GRAD and the Soviet Phobos prototype. The neutron detectors are supplied by Los Alamos National Laboratory and the Soviet Phobos prototype. These are to be carried aboard a gondola that supplies the data and supplies the power for the period of up to two weeks. Author (revised)

TRANSIENT PERFORMANCE OF FAN ENGINE WITH WATER INGESTION Interim Report
S. N. B. Murthy (Purdue Univ., West Lafayette, IN.) and A. Mullican (Purdue Univ., West Lafayette, IN.) Apr. 1993 254 p
(Contracts NAG3-481; DTFA03-83-A-00328; RTOP 505-62-21)
(NASA-CR-190778; E-7709; NAS 1.26:190778; DOT/FAA/CT-TN92/11)
Avail: CASI HC A12/MF A03

In a continuing investigation on developing and applying codes for prediction of performance of a turbine jet engine and its components with water ingestion during flight operation, including power settings, and flight altitudes and speed changes, an attempt was made to establish the effects of water ingestion through simulation of a generic high bypass ratio engine with a generic control. In view of the large effects arising in the air compression system and the prediffuser-combustor unit during water ingestion, attention was focused on those effects and the resulting changes in engine performance. Under all conditions of operation, whether ingestion is steady or not, it became evident that water ingestion causes a fan-compressor unit to operate in a time-dependent fashion with periodic features, particularly with respect to the state of water in the span and the film in the casing clearance space, at the exit of the machine. On the other hand, the aerodynamic performance of the unit may be considered as quasi-steady once the distribution of water has attained an equilibrium state with respect to its distribution and motion. For purposes of engine simulation, the performance maps for the generic fan-compressor unit were generated based on the attainment of a quasi-steady state (meaning steady except for long-period variations in performance) during ingestion and operation over a wide enough range of rotational speeds.

BIBLIOGRAPHY ON PROPULSION AIRFRAME INTEGRATION TECHNOLOGIES FOR HIGH-SPEED CIVIL TRANSPORT APPLICATIONS, 1980-1991
David J. Anderson and Masashi Mizukami Mar. 1993 343 p
(RTOP 537-02-23)
(NASA-TM-105602; E-6938; NAS 1.15:105602) Avail: CASI HC A15/MF A03

NASA has initiated the High Speed Research (HSR) program with the goal to develop technologies for a new generation, economically viable, environmentally acceptable, supersonic transport (SST) called the High Speed Civil Transport (HSCT). A significant part of this effort is expected to be in multidisciplinary systems integration, such as in propulsion airframe integration (PAI). In order to assimilate the knowledge database on PAI for SST type aircraft, a bibliography on this subject was compiled. The bibliography with over 1200 entries, full abstracts, and indexes. Related topics are also covered, such as the following: engine inlets, engine cycles, nozzles, existing supersonic cruise aircraft, noise issues, computational fluid dynamics, aerodynamics, and external interference. All identified documents from 1980 through early 1991 are included; this covers the latter part of the NASA Supersonic Cruise Research (SCR) program and the beginnings of the HSR program. In addition, some pre-1980 documents of significant merit or reference value are also included. The references were retrieved via a computerized literature search using the NASA RECON database system. Author (revised)

SPECIAL TOOLING DISPOSITION FOR AIRCRAFT ENTERING POST PRODUCTION SUPPORT M.S. Thesis
Lee G. Ebert Dec. 1992 53 p
(AD-A261614) Avail: CASI HC A04/MF A01

This thesis identifies and analyzes an important element of Department of Defense (DoD) Post Production Support (PPS) for plan execution: the

disposition of special tooling used to support future manufacturing of aircraft components. As a first step, PPS and its goals are described. Next, the DoD policies for special tooling management are described. Finally, the effects of special tooling disposition are analyzed and a decision process for disposition is presented which incorporates these effects. Further research is recommended to measure the effects tooling disposition decisions have on lead times and manufacturing costs when considering conventional, Rapid Acquisition of Manufactured Parts (RAMP) or Flexible Manufacturing System (FMS) manufacturing methods. AN ANALYSIS OF THE RELIABILITY AND MAINTAINABILITY OF THE JIAN 6 AND JIAN 7 AIRCRAFT AND WAYS TO IMPROVE THEM
Li Zishang and Mao Jingli 27 Jan. 1993 14 p Transl. into ENGLISH from unidentified Chinese document p 2-6
(Contract F33657-88-D-2188)
(AD-A261060; FASTC-ID(RS)T-0628-92) Avail: CASI HC A03/MF A01

Reliability and maintainability are major standards for measuring the superiority of an aircraft. They are major factors in the combat capabilities of the Air Force. Striving to improve and enhance the reliability and maintainability of the aircraft with which the Naval Air Forces are currently primarily equipped, the Jian 6 and the Jian 7, are urgent tasks of Air Force maintenance operations. This article presents a thorough and wide ranging survey of aircraft manufacturing facilities and Naval Air Force Unit plants, and by combining, analyzing and studying this survey, it presents methods and means of improving the reliability and maintainability of the Jian 6 and Jian 7 aircraft. AERONAUTICS IN NACA AND NASA
[1991] 81 p Original contains color illustrations
(NASA-NP-156; NAS 1.83:156) Avail: CASI HC A05/MF A01; 13 functional color pages

Initiated in 1915, the National Advisory Committee for Aeronautics/National Aeronautics and Space Administration (NACA/NASA) aeronautical programs have been the keystone of a sustained U.S. Government, industry, and university research effort which has been a primary factor in the development of our remarkable air transportation systems, the country's largest positive trade balance component, and the world's finest military Air Force. This overview summarizes the flow of events, and the major trends, that have led from the NACA origins to the present NASA Aeronautics program, and indicates some important directions for the years ahead. Derived from text

02 AERODYNAMICS

Computations are presented for one-dimensional, strong shock waves that are typical of those that form in front of a reentering spacecraft. The fluid mechanics and thermochemistry are modeled using two different approaches. The first employs traditional continuum techniques in solving the Navier-Stokes equations. The second-approach employs a particle simulation technique (the direct simulation Monte Carlo method, DSMC). The thermochemical models employed in these two techniques are quite different. The present investigation presents an evaluation of thermochemical models for nitrogen under hypersonic flow conditions. Four separate cases are considered. The cases are governed, respectively, by the following: vibrational relaxation; weak dissociation; strong dissociation; and weak ionization. In near-continuum, hypersonic flow, the nonequilibrium thermochemical models employed in continuum and particle simulations produce nearly identical solutions. Further, the two approaches are evaluated successfully against available experimental data for weakly and strongly dissociating flows. Author (revised)

AN AEROELASTIC MODEL STRUCTURE INVESTIGATION FOR A MANNED REAL-TIME ROTORCRAFT SIMULATION Ph.D. Thesis
William Dean Lewis 1992 295 p
Avail: Univ. Microfilms Order No. DA9303126

Historically, rotorcraft simulations have assumed a model structure incorporating rigid blades and uniform inflow. Advances in computational techniques and rotorcraft theory have enabled the inclusion of higher order model elements into the real-time simulation. This research addresses a model structure assessment of a flexible rotary wing manned flight simulation. The model is a UH-60 blade element simulation. The model possesses a unique capability to provide a variable model structure with consistent matching between structural and aerodynamic theory. The structural model is a representation of the flexible blade based on apriori data. The dynamic inflow model is an adaptation of the Peters and He theory. The investigation methodology consisted of a piloted assessment, frequency domain, and time domain criteria evaluations. Real-time operation permitted a piloted evaluation with rapid alterations to the model structure in question. Frequency response testing permitted an evaluation of the mid to high frequency range. The Comprehensive Identification from Frequency Response (CIFER) program was used for determining the frequency responses. Time domain response was obtained by driving the simulator controls, recording the resultant response, and comparing it to flight test data. This testing methodology was a comprehensive approach which investigated the full range of operation including objective and perceptual fidelity. The CIFER program was invaluable as a frequency response tool. Results indicated that an increase in dynamic wake complexity increased the damping of the heave, pitch and roll channels. Inclusion of blade elasticity reduced the control sensitivity and increased the excitation of existing system modes. The real-time, coupled, simultaneous solution methodology for rotorcraft modeling was superior to previous techniques for off-axis and modal predictions. The previous used model assumptions of rigid blades and uniform inflow resulted in dramatic errors in off-axis response and predictability. The inclusion of second harmonic blade dynamics and dynamic wake is essential for a simulation used in analysis, design, flight test training, and modal prediction. Dissert. Abstr.

COMPUTATIONAL STUDY OF THE AERODYNAMICS AND CONTROL BY BLOWING OF ASYMMETRIC VORTICAL FLOWS OVER DELTA

WINGS Ph.D. Thesis
Kenneth John Craig 1992 126 p
Avail: Univ. Microfilms Order No. DA9302194

The flowfield produced by tangential leading-edge blowing on a rounded leading-edge 60-degree delta wing is investigated computationally by solving the Thin-Layer Navier-Stokes equations. Steady-state flowfields are calculated for various angles of attack and yaw, with and without the presence of tangential leading-edge blowing. The numerical grid is generated using algebraic generation and various interpolation and blending techniques. The jet emanates from a slot with linearly-varying thickness and is introduced into the flowfield using the concept of an actuator plane, thereby not requiring resolution of the jet slot geometry. The Baldwin-Lomax algebraic turbulence model is used to provide turbulent closure. The computational results are compared with those of experiments. The effectiveness of blowing as a rolling moment control mechanism to extend the envelope of controllability is illustrated at different angles of attack. The saturation effect of increased blowing is captured well in the computations. Control reversal noted in similar experimental studies is also observed in the computations. The results are combined in a model by observing the variation of forces and moments with the parameters angle of attack, sideslip angle and blowing momentum coefficient. The model attempts to explain the physical behavior and provides a structured way to study flows of this type. Dissert. Abstr.

SURFACE AND FLOW FIELD MEASUREMENTS IN A SYMMETRIC CROSSING SHOCK WAVE/TURBULENT BOUNDARY-LAYER INTERACTION
D. O. Davis and W. R. Hingst Jun. 1992 20 p Presented at the 10th AIAA Applied Aerodynamics Conference, Palo Alto, CA, 22-24 Jun. 1992; sponsored by AIAA Previously announced in IAA as A92-45574
(RTOP 505-62-52)
(NASA-TM-106086; E-7716; NAS 1.15:106086; AIAA Paper 92-2634)
Avail: CASI HC A03/MF A01

Results of an experimental investigation of a symmetric crossing shock/turbulent boundary layer interaction are presented for a Mach number of 3.44 and deflection angles of 2, 6, 8, and 9 degrees. The interaction strengths vary from weak to strong enough to cause a large region of separated flow. Measured quantities include surface static pressure (both steady and unsteady) and flowfield Pitot pressures. Pitot profiles in the plane of symmetry through the interaction region are shown for various deflection angles. Oil flow visualization and the results of a trace gas streamline tracking technique are also presented. Author

HIGH-ORDER CYCLO-DIFFERENCE TECHNIQUES: AN ALTERNATIVE TO FINITE DIFFERENCES
Mark H. Carpenter and John C. Otto Mar. 1993 29 p
(RTOP 505-70-62-06)
(NASA-TM-107745; NAS 1.15:107745) Avail: CASI HC A03/MF A01

The summation-by-parts energy norm is used to establish a new class of high-order finite-difference techniques referred to here as 'cyclo-difference' techniques. These techniques are constructed cyclically from stable subelements, and require no numerical boundary conditions; when coupled with the simultaneous approximation term (SAT) boundary treatment, they are time asymptotically stable for an arbitrary hyperbolic system. These techniques are similar to spectral element techniques and are ideally suited for parallel implementation, but do not require special collocation points or orthogonal basis functions. The principal focus is on methods of sixth-order formal accuracy or less; however, these methods could be extended in principle to any arbitrary order of accuracy. Author

ROTOR DESIGN OPTIMIZATION USING A FREE WAKE ANALYSIS
Todd R. Quackenbush, Alexander H. Boschitsch, Daniel A. Wachspress, and Kiat Chua Apr. 1993 133 p
(Contract NAS2-13092; RTOP 505-59-36)
(NASA-CR-177612; A-93050; NAS 1.26:177612) Avail: CASI HC A07/MF A02

The aim of this effort was to develop a comprehensive performance optimization capability for tiltrotor and helicopter blades. The analysis incorporates the validated EHPIC (Evaluation of Hover Performance using Influence Coefficients) model of helicopter rotor aerodynamics within a general linear/quadratic programming algorithm that allows optimization using a variety of objective functions involving the performance. The resulting computer code, EHPIC/HERO (HElicopter Rotor Optimization), improves upon several features of the previous EHPIC performance model and allows optimization utilizing a wide spectrum of design variables, including twist, chord, anhedral, and sweep. The new analysis supports optimization of a variety of objective functions, including weighted measures of rotor thrust, power, and propulsive efficiency. The fundamental strength of the approach is that an efficient search for improved versions of the baseline design can be carried out while retaining the demonstrated accuracy inherent in the EHPIC free wake/vortex lattice performance analysis. Sample problems are described that demonstrate the success of this approach for several representative rotor configurations in hover and axial flight. Features that were introduced to convert earlier demonstration versions of this analysis into a generally applicable tool for researchers and designers is also discussed. Author (revised)

Aerospace is the leading positive contributor to this country's balance of trade, derived largely from the sale of U.S. commercial aircraft around the world. This powerfully favorable economic situation is being threatened in two ways: (1) the U.S. portion of the commercial transport market is decreasing, even though the worldwide market is projected to increase substantially; and (2) expenditures are decreasing for military aircraft, which often serve as proving grounds for advanced aircraft technology. To retain a major share of the world market for commercial aircraft and continue to provide military aircraft with unsurpassed performance, the U.S. aerospace industry faces many technological challenges. The field of applied aerodynamics is necessarily a major contributor to efforts aimed at meeting these technological challenges. A number of emerging research results that will provide new opportunities for applied aerodynamicists are discussed. Some of these have great potential for maintaining the high value of contributions from applied aerodynamics in the relatively near future. Over time, however, the value of these contributions will diminish greatly unless substantial investments continue to be made in basic and applied research efforts. The focus: to increase understanding of fluid dynamic phenomena, identify new aerodynamic concepts, and provide validated advanced technology for future aircraft. Author (revised)

GRID SENSITIVITY FOR AERODYNAMIC OPTIMIZATION AND FLOW ANALYSIS Progress report, period ending Dec. 1992
I. Sadrehaghighi and S. N. Tiwari Apr. 1993 120 p
(Contract NCC1-68)
(NASA-CR-192980; NAS 1.26:192980) Avail: CASI HC A06/MF A02

After reviewing relevant literature, it is apparent that one aspect of aerodynamic sensitivity analysis, namely grid sensitivity, has not been investigated extensively. The grid sensitivity algorithms in most of these studies are based on structural design models. Such models, although sufficient for preliminary or conceptional design, are not acceptable for detailed design analysis. Careless grid sensitivity evaluations, would introduce gradient errors within the sensitivity module, therefore, infecting the overall optimization process. Development of an efficient and reliable grid sensitivity module with special emphasis on aerodynamic applications appear essential. The organization of this study is as follows. The physical and geometric representations of a typical model are derived in chapter 2. The grid generation algorithm and boundary grid distribution are developed in chapter 3. Chapter 4 discusses the theoretical formulation and aerodynamic sensitivity equation. The method of solution is provided in chapter 5. The results are presented and discussed in chapter 6. Finally, some concluding remarks are provided in chapter 7. Author

A SIMPLE, APPROXIMATE MODEL OF PARACHUTE INFLATION
J. M. Macha 1992 10 p Presented at the 12th Royal Aeronautical Society/American Institute of Aeronautics and Astronautics (RAS/AIAA) Aerodynamic Decelerator Systems Technical Conference, London, England, 10 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-002465; SAND-92-2282C; CONF-930580-1) Avail: CASI HC A02/MF A01

A simple approximate model of parachute inflation is described. The model is based on the traditional, practical treatment of the fluid resistance of rigid bodies in nonsteady flow, with appropriate extensions to accommodate the change in canopy inflated shape. Correlations for the steady drag and steady radial force as functions of the inflated radius are required as input to the dynamic model. In this approach, the radial force is expressed in terms of easily obtainable drag and reefing fine tension measurements. A series of wind tunnel experiments provides the needed correlations. Coefficients associated with the added mass of fluid are evaluated by calibrating the model against an extensive and reliable set of flight data. A parameter is introduced which appears to universally govern the strong dependence of the axial added mass coefficient on motion history. Through comparisons with flight data, the model is shown to realistically predict inflation forces for ribbon and ringslot canopies over a wide range of sizes and deployment conditions. DOE

INSTABILITY OF FLOW IN A STREAMWISE CORNER Final Report
Manhar R. Dhanak (Florida Atlantic Univ., Boca Raton.) Washington Dec. 1992 18 p Submitted for publication Sponsored by NASA. Langley Research Center
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191410; NAS 1.26:191410; ICASE-92-70) Avail: CASI HC A03/MF A01

The linear stability of an incompressible laminar flow in the blending boundary layer between the boundary layer in a 90 deg streamwise corner and a Blasius boundary layer well away from the corner is examined using a locally parallel flow approximation. It is shown that the influence of the outer boundary conditions associated with oblique modes of disturbances which are anti-symmetric about the bisector plane have a profound effect on the stability of the flow. As a result, in good agreement with observation, the critical streamwise Reynolds number, associated with a spanwise location is significantly reduced as the corner is approached, being R(sub Cr) = 60 approximately for spanwise distance of $z^* = 6x^*R(\text{sup } -1)$ from the corner compared with R(sub Cr) = 322 approximately for $z^* = 20x^*R(\text{sup } -1)$, where x^* measures downstream distance from the leading edges. At R = 600, the growth rate of the most amplified mode of disturbance at the former location is over six times greater than that at the latter; the corresponding wave angle at the two locations is respectively 44 deg and 5 deg, approximately. SUPERSONIC SHOCK WAVE/VORTEX INTERACTION Final Technical Report, 1 Apr. 1989 - 30 Sep. 1992
G. S. Settles and L. Cattafesta Apr. 1993 43 p
(Grant NAG2-575)
(NASA-CR-192917; NAS 1.26:192917) Avail: CASI HC A03/MF A01

Although shock wave/vortex interaction is a basic and important fluid dynamics problem, very little research has been conducted on this topic. Therefore, a detailed experimental study of the interaction between a supersonic streamwise turbulent vortex and a shock wave was carried out at the Penn State Gas Dynamics Laboratory. A vortex is produced by replaceable swirl vanes located upstream of the throat of various converging-diverging nozzles. The supersonic vortex is then injected into either a coflowing supersonic stream or ambient air. The structure of the isolated vortex is investigated in a supersonic wind tunnel using miniature, fast-response, five-hole and total temperature probes and in a free jet using laser Doppler velocimetry. The cases tested have unit Reynolds numbers in excess of 25 million per meter, axial Mach numbers ranging from 2.5 to 4.0, and peak tangential Mach numbers from 0 (i.e., a pure jet) to about 0.7. The results show that the typical supersonic wake-like vortex consists of a non-isentropic, rotational core, where the reduced circulation distribution is self similar, and an outer isentropic, irrotational region. The vortex core is also a region of significant turbulent fluctuations. Radial profiles of turbulent kinetic energy and axial-tangential Reynolds stress are presented. The interactions between the vortex and both oblique and normal shock waves are investigated using nonintrusive optical diagnostics (i.e. schlieren, planar laser scattering, and laser Doppler velocimetry). Of the various types, two Mach 2.5 overexpanded-nozzle Mach disc interactions are examined in detail. Below a certain vortex strength, a 'weak' interaction exists in which the normal shock is perturbed locally into an unsteady 'bubble' shock near the vortex axis, but vortex breakdown (i.e., a stagnation point) does not occur. For stronger vortices, a random unsteady 'strong' interaction results that causes vortex breakdown. The vortex core reforms downstream of the rear stagnation point, and the reduced circulation distribution once again becomes self-similar in this region. A new model of this interaction is proposed. Finally, a curve defining the approximate limits of supersonic vortex breakdown is presented.

THE TRANSIENT DEVELOPMENT OF VORTICES OVER DELTA WINGS Ph.D. Thesis
Othon Kons Rediniotis 1992 359 p
Avail: Univ. Microfilms Order No. DA9304624

An experimental investigation was carried out on the flow over a 75 deg-sweep delta wing. The flowfield over a stationary delta wing at high angles of attack was studied, particularly focusing on breakdown behavior and natural unsteadiness. Static surface pressure measurements on the leeward side of the model were obtained for different Reynolds numbers and angles of attack. Detailed velocity fields, mapped out by a seven-hole probe and two different laser-Doppler velocimetry (LDV) systems, were studied to provide information on the structure of the leading-edge vortices. Comparisons were made of the results obtained using intrusive and non-intrusive techniques. Through surface pressure and velocity power spectra, organized periodic activity in the broken down vortex was detected and studied. The flowfield over a delta wing performing dynamic pitch-up motions was also investigated. Unsteady surface pressures were measured and compared with the steady case pressure distributions. The unsteady velocity field on different planes was mapped out using a specially manufactured and calibrated fast-response seven-hole probe as well as a 3-D and a 3-D laser-Doppler velocimeter. The transient development of the leading-edge vortices in terms of velocity and vorticity distribution was carefully studied. The flowfield in the wake of the delta wing was also examined at angles of attack as high as alpha = 90 deg, using hot-wire anemometry and flow visualization. Periodic vortex shedding was detected and its characteristics, such as Strouhal number variation and modes of shedding, were studied. Dissert. Abstr.

AERODYNAMIC FOUNDATIONS FOR USE OF UNSTEADY AERODYNAMIC EFFECTS IN FLIGHT CONTROL Ph.D. Thesis
Thomas Eugene McLaughlin 1992 177 p
Avail: Univ. Microfilms Order No. DA9304582

Unsteady aerodynamic effects have long been postulated as a means to enhance low speed performance of aircraft. Lift coefficients as high as

four to five times greater than the steady state values are possible. However, before the phenomenon can be exploited, the temporal nature of these forces must be quantified and predicted over the widest possible range of forcing conditions. Unsteady aerodynamic force generation collected from numerous experimental efforts was examined over a wide range of non-dimensional pitch rates, Reynolds numbers, mach numbers, and sinusoidal and constant rate motion histories. Airfoils tested included those of varying camber and with two- and three-dimensional geometries. Unsteady aerodynamic forces were found to change linearly with non-dimensional time. The duration of the unsteady event was found to be a function only of non-dimensional pitch rate or frequency, and of the initial state of the airfoil. Force magnitudes generated at any given time in the event were found to depend simply on the same parameters and on airfoil static characteristics. Sinusoidal and constant rate pitch motions were found to produce very similar force histories. Increasing airfoil sweep improved the duration of the unsteady event. In all cases, the unsteady forces produced were found highly predictable and well-correlated across the range of forcing parameters. These findings offer a basis on which flight control algorithms may be developed to increase aircraft low speed turn performance.

A NUMERICAL AND EXPERIMENTAL STUDIES OF FLOW CHARACTERISTICS IN CENTRIFUGAL FANS Ph.D. Thesis
Linxi Xia 1992 282 p
Avail: Univ. Microfilms Order No. DA9234032

Flow characteristics, performances, and noises of centrifugal fans were studied. The work can be grouped as: (1) experimentally examining the flow structure downstream of the impeller and its relationship with noise characteristics; (2) numerically simulating the flow field in impeller and fan housings, and establishing their aerodynamic design criteria; and (3) exploring new and more accurate sound rating and low-frequency fluctuation simulation methods. The objective is to increase understanding of fan aerodynamic noise generation mechanism, to advance engineering analysis and design tools, and to improve the efficiency and acoustic performances of the current centrifugal fans. The test results showed that the fan components designed with the proposed aerodynamic design method have 5 percent efficiency improvement and 3-15 dB noise reduction over the current designs. Also, the design effectiveness was increased significantly compared with the traditional fan design methods. Dissert. Abstr.

NUMERICAL SIMULATION OF LEADING-EDGE RECEPTIVITY TO FREESTREAM VORTICITY Ph.D. Thesis
Thomas Alan Buter 1992 199 p
Avail: Univ. Microfilms Order No. DA9237239

The receptivity to freestream vorticity of the boundary layer over a flat plate with an elliptic leading edge is investigated numerically. The flow is simulated by solving the incompressible Navier-Stokes system in general curvilinear coordinates with the vorticity and stream function as dependent variables. A finite-difference scheme which is second-order accurate in both space and time is used. As a first step, the steady basic-state solution is computed. Then a small-amplitude vortical disturbance is introduced at the upstream boundary and the governing equations solved time accurately to evaluate the spatial and temporal growth of the perturbations leading to instability waves (Tollmien-Schlichting waves) in the boundary layer. Disturbance amplitude, orientation, the effect of the leading edge and of juncture curvature are investigated for the case of spanwise vorticity. Simulations reveal, for the conditions considered, a linear variation in the TS response with forcing amplitude for a perturbation of the freestream velocity which is either symmetrical or asymmetrical with respect to the basic-state stagnation streamline. The presence of a large transverse component of velocity along the basic-state stagnation streamline for the case of an asymmetrical perturbation of velocity results in the appearance of a superharmonic component near the nose. This superharmonic decays rapidly along the nose for the flow conditions considered. In all cases considered, the first clear appearance of the TS mode occurs aft of the surface pressure-gradient maximum in the juncture region. Changes to the geometry which increase the maximum the basic-state pressure gradient near the juncture are found to increase receptivity.

Dissert. Abstr.

COMPUTATION OF TRANSONIC FLOW OVER A POROUS SURFACE PROJECTILE Ph.D. Thesis
Jih-Lan Hsiung 1992 144 p
Avail: Univ. Microfilms Order No. DA9304565

A numerical tool is constructed to predict the aerodynamic performance of a projectile, and to examine the effects of making a part of the projectile surface porous on its performance in the transonic regime, 0.9 less than M less than 1.2. The code developed in this study, POROUS, includes the Darcy's law describing the flow through a porous surface and a turbulence model taking the transpiration effect into consideration. The computed results for transonic flow over a solid secant-ogive-cylinder-boattail (SOCBT) projectile show good agreements with experimental data in both pressure coefficient distribution and shock wave location. For the Mach numbers and angles of attack that have been examined so far for the solid SOCBT, the surface pressure predicted by our POROUS code is found to be more accurate than those by other numerical and semi-empirical codes. The passive control technique by using porous surface to reduce the total drag of a projectile has been investigated here for Mach numbers from 0.90 to 1.2 and angles of attack 0 to 4 degrees. The porous surface works very well in drag reduction at subsonic Mach numbers 0.94-0.98 when there are strong shocks on the boattail. At Mach 0.96, a total drag reduction as high as 28.43 percent has been achieved with properly selected porous surfaces. With an angle of attack, the efficiency of drag reduction can be improved if splitters are placed in the cavity, and the lift may also be increased. According to the present analysis, having porous surfaces of uniform porosity on both cylinder and boattail is found to be the most efficient arrangement. The total drag decreases with increasing maximum porosity factor, whose limiting value has been determined. The porosity is more effective if the original shock on the solid projectile is near the rear of the porous region on the cylinder; otherwise, efficiency increases with the length of the porous surface. Dissert. Abstr.

AN EXPERIMENTAL STUDY OF UNDER-EXPANDED JETS Ph.D. Thesis
Terrence M. Cain 1991 156 p
Avail: Univ. Microfilms Order No. BRD-98281

Experiments were conducted on turbulent under-expanded jets of nitrogen and carbon dioxide exhausted into still air from Mach 3 and Mach 5 conical nozzles. The ratio of the stagnation pressure in the nozzle to the static pressure in the receiving tank was of the order 10(exp 3) which is a condition representative of rocket exhaust plumes generated at altitudes near 20 km. The Oxford gun tunnel was adapted for the project by attaching a small nozzle to its barrel. Jets were generated in the tunnel's test section, photographed with a schlieren system and traversed by a Pitot probe. The traverse mechanisms developed for this work allow 100 mm travel during the period of 20 ms over which the tunnel stagnation pressure is constant. Methods of increasing this steady period (the test time) by modification of the tunnel's driver tube are suggested after a detailed investigation of the tunnel's operation. Pitot pressure surveys which reveal the plume structure and provide information about the turbulent mixing downstream of the first shock cell are presented. The measurements in plumes at various pressure ratios are correlated by normalizing the probe position with the size of the first shock cell and normalizing the Pitot pressure by the pressure in the receiver. The characteristics of under-expanded jets are summarized and available experimental data is reviewed and classified using recently published plume similarity parameters. The asymmetrical nature of plumes is discussed and a physical explanation for plume shock layer instability is given. Condensation of the plume gas is investigated by reference to previous experiments and theoretical models. It is shown that it is unlikely that condensation occurred anywhere within the nitrogen plumes as drop growth rates are negligible at high entropy. Method of characteristics (MOC) calculations of the initial plume expansion were compared with the Pitot measurements in the plume core. Variation of the nozzle exit conditions used for the boundary conditions of the MOC predictions is used to demonstrate that viscous and two-dimensional effects within the nozzle were not very significant. Dissert. Abstr.

EXPERIMENTAL AND COMPUTATIONAL INVESTIGATION OF HELIUM INJECTION INTO AIR AT SUPERSONIC AND HYPERSONIC SPEEDS

Ph.D. Thesis
Eric James Fuller 1992 187 p
Avail: Univ. Microfilms Order No. DA9233626

Experiments were performed to determine the mixing rate and core penetration of the injectant and the flow field total pressure losses when gaseous injection occurs into a supersonic freestream. Tested in a freestream Mach number of 3.0 and a freestream Reynolds number of 5.0 x 10(exp 7)/m, was a single, sonic 5x underexpanded helium jet with a transverse angle of 30 degrees, and rotated from 0 to -28 degrees to test injector yaw effects. Tested at Mach 6.0 with a freestream Reynolds number of 5.4 x 10(exp 7)/m, was an array of three supersonic, 5x underexpanded helium injectors with an exit Mach number of 1.7 and a transverse angle of 15 degrees. This injector array was tested at yaw angles of 0 and -15 degrees. Surface flow visualization showed that significant flow asymmetries were produced by injector yaw. Nanosecond exposure shadowgraph pictures showed the injection plume to be unsteady, and further studies demonstrated this unsteadiness to be related to observed shock waves orthogonal to the injectant bow shock, generated at a frequency of 30 kHz. The primary data technique was a concentration probe which measured the flow field molar concentration of helium. Concentration and meanflow data were taken at several downstream stations and yielded contours of helium concentration, total pressure, Mach number, as well as other flow field properties. The injectant mixing rates, expressed as the maximum concentration decay rates, and mixing distances were found to be unaffected by injector yaw, in the Mach 3.0 experiments, but adversely affected by injector yaw in the Mach 6.0 experiments. One promising aspect of injector yaw was that as the yaw angle was increased, lateral motion of the injectant plume became significant, and the turbulent mixing region increased by approximately 34 percent. Comparisons of the 15 degree injection into a Mach 6.0 flow to previous experiments with 15 degree injection into a Mach 3.0 freestream, demonstrated that there was a significant decrease in initial mixing, at Mach 6.0, resulting in a much longer mixing distance. From a parametric computational study of the Mach 6.0 experiments, the effects of adjacent injectors was found to decrease lateral spreading while increasing the vertical penetration of the injectant plume, and marginally increasing the injectant core decay rate. Dissert. Abstr.

N93-25542 Stanford Univ., CA.
NAVIER-STOKES SIMULATIONS OF UNSTEADY TRANSONIC FLOW PHENOMENA Ph.D. Thesis
Christopher Alexande Atwood 1992 131 p
Avail: Univ. Microfilms Order No. DA9234053

Numerical simulation of two classes of unsteady flows are obtained via the Navier-Stokes equation: a blast-wave/target interaction problem class and a transonic cavity flow problem class. The method developed for the viscous blast-wave/target interaction problem assumes a laminar, perfect gas implemented in a structured finite-volume framework. The approximately factored implicit scheme uses Newton subiterations to obtain the spatially and temporally second-order accurate time history of the interaction of blast-waves with stationary targets. The inviscid flux is evaluated using either of two upwind techniques, while the full viscous terms are computed by central differencing. Comparisons of unsteady numerical, analytical, and experimental results are made in two- and three-dimensions for Couette flows, a starting shock-tunnel, and a shock-tube blocking study. The results show accurate wave speed resolution and nonoscillatory discontinuity capturing of the predominantly inviscid flows. Viscous effects were increasingly significant at large post-interaction times. While the blast-wave/target interaction problem benefits from high resolution methods applied to the Euler terms, the transonic cavity flow problem requires the use of an efficient scheme implemented in a geometrically flexible overset mesh environment. Hence, the Reynolds averaged Navier-Stokes equations implemented in a diagonal form are applied to the cavity flow class of problems. Comparisons between numerical and experimental results are made in two-dimensions for free shear layers and both rectangular and quieted cavities, and in three-dimensions for Stratospheric Observatory For Infrared Astronomy (SOFIA) geometries. The acoustic behavior of the rectangular and three-dimensional cavity flows compare well with experiment in terms of frequency, magnitude, and quieting trends. However, there is a more rapid decrease in computed, acoustic energy with frequency than observed experimentally owing to numerical dissipation. In addition, optical phase distortion due to the time-varying density field is modelled using geometrical constructs. The computed optical distortion trends compare with the experimentally inferred result, but underpredicts the fluctuating phase difference magnitude. Dissert. Abstr.

N93-25545 Stanford Univ., CA.
TANGENTIAL FUSELAGE BLOWING ON AN OGIVE CYLINDER Ph.D. Thesis
Gabriel Ivan Font 1992 193 p
Avail: Univ. Microfilms Order No. DA9234095

The nose vortices of aircraft or missiles tend to become asymmetric at high angles of attack producing a side force which is destabilizing to the body. A jet located near the nose and blown tangentially to the fuselage has the ability to alter the flow field and diminish the unwanted side force. Alternatively, it can produce a large side force which can be used for improving the maneuverability of the vehicle. This work explores the effects of tangential blowing on the vortical structures that develop about the fuselage of a missile or aircraft at a high angle of attack. A tangent-ogive cylinder configuration was used to allow comparison with experiments. The study was carried out numerically by solving the Thin-Layer, Reynolds-Averaged, compressible Navier-Stokes equations. A zonal method was used to solve the equations. The jet was implemented with an actuator plane. Computations were conducted in a fully laminar and a fully turbulent manner. Appropriate algebraic turbulence models were used for the jet and the boundary layers in the turbulent computations. The study was conducted at a Reynolds number, based on diameter, of 52000, and Mach number of 0.2. The angles of attack used were 10, 30 and 45 deg. The influence of slot location were also explored. This study confirmed that large side forces could be generated from tangential blowing even at low angles of attack. Several conclusions were made concerning the physical mechanisms by which the jet interacts with the ambient flow field to produce a side force: (1) A pressure gradient normal to the surface is created near the wall due to the momentum of the jet being forced to follow the curvature of the surface. (2) A large amount of vorticity is added to the flow field by the jet. In the region of the slot, the vorticity has the effect of inducing circulation around the body. Downstream of the slot, the vorticity alters the strength of the nose vortices. And (3), the position of the nose vortices can be altered by the actions of the jet.

AN INVESTIGATION ON PLANAR VELOCIMETRY BY SPATIAL CROSS-CORRELATION Ph.D. Thesis
Philip Andrew Fawcett 1992 213 p
Avail: Univ. Microfilms Order No. DA9303118

Advances in rotorcraft aerodynamics require the ability to measure instantaneous velocity fields with high temporal resolution over large areas. Existing measurement techniques are not adequate for such flows. This thesis explores planar velocimetry by spatial cross correlation. The spatial cross correlation is determined between two flowfield images separated by a known time delay. Unlike existing particle image velocimetry (PIV) techniques, there is no need to resolve individual particles. Instead, patterns of scattered light intensity are used to determine statistical correlations. With this process, the time required to measure velocity fields is vastly reduced. The post-processing is reduced to a completely computational procedure which takes advantage of the rapid advances in computer technology. This technique is seen to be a superset of PIV and laser speckle techniques. Numerical simulations were used to prove that the technique gives correct results with deterministic and random data, and it performs accurately despite the presence of high levels of noise. Initial experimental validation was performed using a moving solid surface with a random, fine grained pattern. The technique was next extended to the measurement of steady and unsteady flows in a water table with a standard video camera and ambient lighting. Low-speed and then high-speed air flows were measured using light sources ranging from a high-powered, pulsed, copper vapor laser to a 9 volt flashlight. A variety of imaging and computer equipment investigated during the development of SCV is described in the thesis along with the chronology of the experiments. The final form of the system is described in detail and consists of a dual camera imaging system coupled with an MS-DOS based computer and video digitizing board. Three advanced applications were used successfully to study the capabilities of the technique. The first was the flow around a wing of high aspect ratio executing plunging motion of large amplitude and high-rate in

a wind tunnel. The second was the quantification of the time history of velocity around a canard-wing configuration during continuous changes in canard position. The final application was the study of the highly three dimensional unsteady wake of a rotor in forward flight. Iterative computational algorithms for enhancing the statistical accuracy and spatial resolution are described. Dissert. Abstr.

ANALYSIS OF WING WAKE ROLL-UP USING A VORTEX-IN-CELL METHOD Ph.D. Thesis
Renato Silva Ribeiro 1992 213 p
Avail: Univ. Microfilms Order No. Da9234153

A wing producing lift generates a thin vorticity sheet behind it, called a vortex wake. This wake is convected downstream, adjusting its shape in order to remain force-free, and can interact with other surfaces and wakes as it does so. The determination of wake geometries and effects are of great interest in several aircraft design problems, including analysis of canard-wing interference, rotors and propeller-wing interference. This work applies a vortex-in-cell method to a singularity model for wings and wakes in steady, incompressible flow. Wings are represented by a vortex-lattice model, while wakes are formed by line vortices. The vorticity contained in the singularities is spread onto a rectangular grid, using quadratic splines based on the grid-cell dimensions. Velocities are computed from the vorticity field by an infinite boundary Fast Poisson Solver, which employs fast Sine and Cosine transforms and a boundary convolution scheme. Although the grid boundaries are placed close to the singularities, the solution is consistent with the condition of vanishing perturbations at infinity. Provisions are made to take into account portions of the wakes downstream of the grid box. Velocities at points inside the grid are obtained by interpolation. The result is the removal of infinite velocities, as if a infinite vortex-core model were introduced. The velocities computed with the vortex-in-cell method are used to relax the wake and to correct the singularity strengths on the wing, in a mixed iterative procedure. Several problems are studied to evaluate the performance of the method: velocity induced by single infinite and semi-infinite vortices, lift of rectangular and swept-back wings, roll-up of single wing wakes and interaction between wings and wakes in various arrangements. Solutions for these problems were compared with results from experiments and other methods. Detailed descriptions for wake geometry and accurate load distributions were obtained, even for cases where wakes intercepted wings directly. The method provides velocity values throughout the grid as part of the solution. The computational time required is controlled by the number of grid cells, not the number of singularities.

AN INVESTIGATION OF PHOTOTHERMAL VELOCIMETRY FOR APPLICATION TO TRANSIENT, HIGH-SPEED GAS FLOWS Ph.D. Thesis
Theodore Philip Delianides 1992 144 p
Avail. Univ. Microfilms Order No. DA9234084

The measurement of velocity is fundamental to the study of fluid mechanics. Though much can be learned from flow visualization, a better understanding of a flow phenomenon requires the measurement of velocity and thermodynamic properties. In the modern gas-dynamics laboratory, bulky physical probes such as hot-wire anemometers and pitot tubes that were for many years the only means of measuring velocity have been supplemented by optical diagnostic techniques which are nonintrusive, have high spatial and temporal resolutions, and are capable of rapid data acquisition rates. From a flow-diagnostician's viewpoint, perhaps the most challenging flows are transient ones, that is, those exhibiting large-scale flow-structure variations with time. Unfortunately, the existing optical diagnostic techniques for velocity measurement are not well-suited for studying high-speed, transient flows. They are either too intrusive by nature or limited in their applicability because the various optical phenomena on which they are based are adversely affected by flow conditions. A new and potentially powerful velocimetry technique has been developed that is based on the heating that accompanies intermolecular quenching collisions. It uses a pulsed laser tuned to an absorption band of a seed species to create a thermally-tagged line in a flow. The line is tracked spatially and temporally using a refractive-index-sensitive imaging system. In the current work, thermal tags are created with a pulsed carbon dioxide laser in flows of nitrogen gas seeded with a small fraction of sulfur hexafluoride and are tracked either with a schlieren or shadowgraph imaging system. An initial investigation of the quasi-steady flow from an axisymmetric nozzle yield velocity measurements that compare well to pitot tube measurements at the same positions. The flow induced by a propagating normal shock wave is also studied, and measurements are reported of the velocity directly behind a shock wave as it exits a shock tube. The first application of the new technique is to the study of a 100 percent-duty-cycle-pulsed, high-speed axisymmetric jet. Axial velocity profiles at various times and spatial positions are presented, with peak velocities exceeding 300m/sec. For a mechanically-valve-actuated pulse jet, this is the highest output flow velocity ever investigated. Dissert. Abstr.

INITIAL STREAMWISE VORTICITY FORMATION IN A TWO-STREAM MIXING LAYER Ph.D. Thesis
Chao-Hung Steve Tung 1992 240 p
Avail. Univ. Microfilms Order No. DA9235931

The formation and evolution of streamwise vortices in a two-stream mixing layer were experimentally investigated. The formation and pairing of the spanwise coherent structures were stabilized by acoustic excitation so that they occurred at fixed streamwise locations. The forcing signal consisted of two frequency components: the initial instability frequency and its first subharmonic. The latter also served as the triggering signal and phase reference for A/D sampling. No artificial spanwise forcing was applied but small disturbances originating from the splitter plate were allowed to develop with the mixing layer. Time traces of three velocity components on a two-dimensional grid of locations were recorded by hot-wire anemometry with an x-wire probe at successive streamwise stations. From these, three-dimensional distributions of ensemble-average spanwise and streamwise vorticities were computed and analyzed. The spanwise coherent structures remained quasi-two-dimensional from the initial roll-up to the end of the first structure amalgamation. During this process, the structure spacing changed from the initial instability wavelength to the first subharmonic wavelength. Concentrated streamwise vortices were first observed at the start of the first spanwise structure pairing. They appeared on the peripheries and between the amalgamating spanwise structures at isolated spanwise locations. Downstream, additional vortices were generated at spanwise locations adjacent to the original vortices, which remained at the same spanwise locations. These structures formed counter-rotating pairs located alternately along the spanwise direction. Their three-dimensional vorticity distributions agree with the interwinding-vortex-line model previously proposed by others. The upstream spacing between streamwise vortices of the same sign was about 2/3 of the initial instability wavelength of the spanwise structures. Near the end of the spanwise structure amalgamation, pairing between streamwise vortices of the same sign occurred. However, this phenomenon did not take place uniformly over the entire span of measurement. As a result, global doubling in spanwise wavelength did not occur when the streamwise wavelength doubled. Turbulent bursts were first observed in the regions occupied by the spanwise structures near the completion of the first amalgamation. Results from the present study were inconclusive in relating these bursts to the presence of streamwise structures in those regions. Dissert. Abstr.

A NEW LU-SGS FLOW SOLVER FOR CALCULATING REENTRY FLOWS Ph.D. Thesis
David Ramos Olynick 1992 192 p
Avail: Univ. Microfilms Order No. DA9303674

An LU-SGS flow solver is developed and evaluated. The LU-SGS method of Yoon is adapted to calculate axisymmetric, chemically reacting, and weakly ionized flowfields characteristic of reentry vehicles. Modifications are presented that improve the numerical efficiency and stability of the LU-SGS scheme for the calculation of nonequilibrium reacting flows. A parallel effort is made to improve the physical modeling of the flowfield. A new two-temperature dissociation model is derived from kinetic theory to account for the coupled vibration-dissociation process. The model minimizes uncertainties associated with the Park two-temperature model. The effects of the model on AOTV type flowfields are examined. The accuracy of the continuum equations employed are examined by comparing with numerical flow solutions generated using the Direct Simulation Monte Carlo (DSMC) method. For this comparison, a four temperature thermal model is employed that allows the calculation of separate translational, rotational, vibrational, and electron-electronic temperatures. Calculations were made for flows

with and without ionization over the Project Fire 2 vehicle. For the Project Fire 2 conditions considered (76 km and above), assuming the translational temperature equal to rotational temperature and the vibrational temperature equal to the electron-electronic temperature were found to be poor approximations. Surface convective heat transfer for a number of Fire 2 flow calculations are compared. The trends of the Fire 2 experimental data were predicted and the present numerical results compared well with solutions from other Computational Fluid Dynamic (CFD) codes and the DSMC method. The effects of a number of flow phenomena on the convective surface heating are examined. For the Fire 2 conditions considered, the flow was almost fully dissociated. As a result, the recombination of nitrogen was found to have the most influence on the surface heating rates. Other phenomena such as changing the thermal model, transport model, number of species, and chemical rates had little effect on the surface convective heat transfer rates. Finally, the computational efficiency of the present method is compared to the Gauss-Siedel line relaxation method of Candler. CPU costs for each method are calculated for inviscid and viscous flows in thermal and chemical nonequilibrium over a cylinder. Total CPU costs for the methods were found to be comparable for the inviscid calculation. However, the Gauss-Siedel method was found to be much faster than the present LU-SGS scheme for viscous flow calculations. Dissert. Abstr.

STATIONARY CROSSFLOW INSTABILITY ON AN INFINITE SWEPT WING Ph.D. Thesis
Ray-Sing Lin 1992 220 p
Avail: Univ. Microfilms Order No. DA9237268

The Swept Laminar Flow Wing has long been a goal for aerodynamic scientists and engineers. Here the ideas of Laminar Flow Control (LFC) are applied to delay transition and maintain laminar flow over a much larger fraction of a wing surface. When applied to a swept wing, a configuration adopted by current-generation civil-transport aircraft, a significant reduction in drag and substantial increase in energy efficiency could result. To successfully apply this technology, a thorough knowledge and understanding of the transition process on the swept wing is necessary. Because the boundary-layer flow over a swept wing is highly three-dimensional (3-D), streamwise co-rotating crossflow vortices exist, which strongly affect the transition of laminar flow to turbulent. In this work, the stability of the flow over a 70 degree swept, infinite-span wing is examined both by quasi-parallel linear stability theory and by numerically solving the 3-D unsteady incompressible Navier-Stokes (N-S) equations in primitive-variable form. Near the leading edge, steady blowing and suction of chosen wavelength in the spanwise direction is introduced on the wall surface to simulate surface irregularity and generate an instability. The linear stability problems are solved by a Chebyshev-collocation method, while the 3-D full N-S simulation is accomplished by a Fourier-spectral/finite-difference/multiple-grid scheme (developed by the author), which is shown to be accurate and robust. Results of the linear stability analysis indicate that the convex wall curvature has a stabilizing effect while the streamline curvature has a destabilizing effect on the stationary crossflow vortices. The results of direct N-S simulation support the so-called crossflow/crossflow structure which is a consequence of nonlinear interaction near the wall. Strong spanwise modulation of the streamwise-velocity profiles results in the appearance of multiple inflection points. A detailed comparison of the N-S calculation with linear theory and experimental results is provided. Dissert. Abstr.

SIMULATION OF VORTEX BURSTING Ph.D. Thesis
Jiak-Kwang Tan 1992 164 p
Avail: Univ. Microfilms Order No. DA9301391

The 3-D, incompressible, time-dependent Navier-Stokes equations in primitive variables are used to simulate bursting of a line vortex embedded in a unbounded uniform flow. The entire study is divided into three parts. First, the steady axisymmetric vortex behavior with various swirl level is studied. At low swirl level, the vortex flow remains parallel and can be described by the quasi parallel equations. At higher swirl levels, the flow develops large amplitude waves. When the amplitude of these waves is large enough, recirculation bubbles will occur on the vortex axis. The flow within the recirculation bubbles is found to nearly obey the Prandtl-Batchelor's conditions. Secondly, the spatial and temporal evolution of axisymmetric vortex breakdown is investigated. When the swirl and Reynolds number are small, asymptotically steady flows develop, with steady recirculation bubbles at the higher swirl. When the swirl and Reynolds number are high enough, ring vortices are shed periodically from the primary (mostly steady) bubble, much as would happen from a bluff body. A steady/unsteady boundary dividing asymptotically steady and unsteady flow is constructed in the swirl parameter vs Reynolds number plane. It appears that the high Reynolds number limit of the boundary is at the swirl level corresponding to Benjamin's vortex criticality condition. As Reynolds number decreases, the swirl level required to induce unsteady flow increases. The Strouhal number of the shed vortices is about .2, independent to both the swirl parameter and Reynolds number. Lastly, 3-D stability of the steady and unsteady axisymmetric flows at some selected swirl parameter and at a constant Reynolds number, is examined. A small, but finite, first harmonic perturbation is introduced and the behavior of the flow is simulated by solving the full 3-D Navier-Stokes equations. At low swirl level, where quasi parallel is valid, the flow is found to be stable to 3-D perturbations. At higher swirl, where the quasi parallel approximation fails and the axisymmetric flow is wavy but has no bubble, the flow evolves into a spiral type of vortex breakdown. At even higher swirl, where recirculation bubbles occur, the first recirculation bubble is found to be stable to 3-D perturbations, but not the second one. Asymmetric amplification is concentrated at the second bubble. Hence, the flow has the appearance of bubble breakdown upstream and a downstream spiral breakdown. When the axisymmetric solution exhibits regular vortex shedding behavior, the shed ring vortices are found to be stretched and spiraling around an almost axisymmetric core. The flow appears to have a front end axisymmetric bubble, followed by a spiraling tail. When spiraling occurs, the first harmonic component dominates the asymmetric motion. Dissert. Abstr.

ESTIMATING TURBINE LIMIT LOAD Final Report
Arthur J. Glassman Apr. 1993 10 p
(Grant NAG3-1165; RTOP 505-69-50)
(NASA-CR-191105; E-7705; NAS 1.26:191105) Avail: CASI HC A02/MF A01

A method for estimating turbine limit-load pressure ratio from turbine map information is presented and demonstrated. It is based on a mean line analysis at the last-rotor exit. The required map information includes choke flow rate at all speeds as well as pressure ratio and efficiency at the onset of choke at design speed. One- and two-stage turbines are analyzed to compare the results with those from a more rigorous off-design flow analysis and to show the sensitivities of the computed limit-load pressure ratios to changes in the key assumptions. NUMERICAL SIMULATION OF HYPERSONIC AERODYNAMICS AND THE COMPUTATIONAL NEEDS FOR THE DESIGN OF AN AEROSPACE PLANE
S. K. Liu 1992 147 p
(Contract F49620-91-C-0003)
(AD-A260681; RAND/N-3253-AF) Avail: CASI HC A07/MF A02

This Note records the results of a review and analysis of the status of the computational fluid dynamic (CFD) modeling techniques related to the National Aerospace Plane (NASP) operation. It was undertaken as a task in the study, The National Aerospace Plane (NASP): Development Issues for Follow-on Systems, performed within the Technology Applications Program of Project AIR FORCE. The research sought to evaluate independently the degree of uncertainty and the technical risk involved in predicting the NASP performance using numerical simulation of aerothermal and chemical/combustion processes. This Note covers the technical review portion and identifies the areas for research emphasis so that the predictive reliability of the NASP's potential performance parameters can be improved. This study should interest those concerned with the aerospace plane development in general, and hypersonic CFD modeling in particular. DTIC

REDUCTION IN SIZE AND UNSTEADINESS OF A VTOL GROUND VORTEX BY GROUND FENCES
John M. Cimbala, Michael L. Billet, and Todd B. Harman 15 Apr. 1993 23 p

(Grant NAG2-484)
(NASA-CR-192997; NAS 1.26:192997) Avail: CASI HC A03/MF A01

A ground vortex, produced when a jet impinges on the ground in the presence of cross flow, is encountered by V/STOL aircraft hovering near the ground and is known to be hazardous to the aircraft. The objective of this research was to identify a ground-based technique by which both the mean size and fluctuation in size of the ground vortex could be reduced. A simple passive method was identified and examined in the laboratory. Specifically, one or two fine wire mesh screens (ground fences) bent in a horseshoe shape and located on the ground in front of the jet impingement point proved to be very effective. The ground fences work by decreasing the momentum of the upstream-traveling wall jet, effectively causing a higher freestream-to-jet velocity ratio (V(sub infinity)/V(sub j)) and thus, a ground vortex smaller in size and unsteadiness. At(V(sub infinity)/V(sub j)) = 0.15, the addition of a single ground fence resulted in a 70 percent reduction in mean size of the ground vortex. With two ground fences, the mean size decreased by about 85 percent. Fluctuations in size decreased nearly in proportion to the mean size, for both the single and double fence configurations. These results were consistent over a wide range of jet Reynolds number (10(exp 4) less than Re(sub jet) less than 10(exp 5)); further development and full-scale Reynolds number testing are required, however, to determine if this technique can be made practical for the case of actual VTOL aircraft. EXPERIMENTAL EFFECTS OF WING LOCATION ON WING-BODY PRESSURES AT SUPERSONIC SPEEDS
Jerry M. Allen and Carolyn B. Watson Apr. 1993 198 p
(RTOP 505-59-30-01)
(NASA-TM-4434; L-17148; NAS 1.15:4434) Avail: CASI HC A09/MF A03

An experimental study was performed at supersonic speeds to measure wing and body spanwise pressure distributions on an axisymmetric-body delta wing model on which the wing vertical location on the body was systematically varied from low- to high-mounted positions. In addition, for two of these positions both horizontal and radial wing angular orientations relative to the body were tested, and roll angle effects were investigated for one of the positions. Seven different wing-body configurations and a body-alone configuration were studied. The test was conducted at Mach numbers from 1.70 to 2.86 at angles of attack from about -4 deg to 24 deg. Pressure orifices were located at three longitudinal stations on each wing-body model, and at each station the orifices were located completely around the body, along the lower surface of the right wing (looking upstream), and along the upper surface of the left wing. All pressure coefficient data are tabulated and selected samples are shown graphically to illustrate the effects of the test variables. The effects of angle of attack, roll angle, Mach number, longitudinal station, wing vertical location, wing angular orientation, and wing-body juncture are analyzed. The vertical location of the wing on the body had a very strong effect on the body pressures. For a given angle of attack at a roll angle of 0 deg, the pressures were virtually constant in the spanwise direction across the windward surfaces of the wing-body combination. Pressure-relieving, channeling, and vortex effects were noted in the data. Author (revised)

(NASA-TM-104001; A-93040; NAS 1.15:104001) Avail: CASI HC A14/MF A03

The jet-induced forces generated on short takeoff and vertical landing (STOVL) aircraft when in close proximity to the ground can have a significant effect on aircraft performance. Therefore, accurate predictions of these aerodynamic characteristics are highly desirable. Empirical procedures for estimating jet-induced forces during the vertical/short takeoff and landing (V/STOL) portions of the flight envelope are currently limited in accuracy. The jet-induced force data presented significantly add to the current STOVL configurations data base. Further development of empirical prediction methods for jet-induced forces, to provide more configuration diversity and improved overall accuracy, depends on the viability of this STOVL data base. The data base may also be used to validate computational fluid dynamics (CFD) analysis codes. The hover data obtained at the NASA Ames Jet Calibration and Hover Test (JCAHT) facility for a parametric flat-plate model is presented. The model tested was designed to allow variations in the planform aspect ratio, number of jets, nozzle shape, and jet location. There were 31 different planform/nozzle configurations tested. Each configuration had numerous pressure taps installed to measure the pressures on the undersurface of the model. All pressure data along with the balance jet-induced lift and pitching-moment increments are tabulated. For selected runs, pressure data are presented in the form of contour plots that show lines of constant pressure coefficient on the model undersurface. Nozzle-thrust calibrations and jet flow-pressure survey information are also provided. Author (revised)

CONICAL EULER ANALYSIS AND ACTIVE ROLL SUPPRESSION FOR UNSTEADY VORTICAL FLOWS ABOUT ROLLING DELTA WINGS
Elizabeth M. Lee-Rausch and John T. Batina Mar. 1993 30 p Original contains color illustrations
(RTOP 505-63-50-12)
(NASA-TP-3259; L-17059; NAS 1.60:3259) Avail: CASI HC A03/MF A01; 3 functional color pages

A conical Euler code was developed to study unsteady vortex-dominated flows about rolling, highly swept delta wings undergoing either forced motions or free-to-roll motions that include active roll suppression. The flow solver of the code involves a multistage, Runge-Kutta time-stepping scheme that uses a cell-centered, finite-volume, spatial discretization of the Euler equations on an unstructured grid of triangles. The code allows for the additional analysis of the free to-roll case by simultaneously integrating in time the rigid-body equation of motion with the governing flow equations. Results are presented for a delta wing with a 75 deg swept, sharp leading edge at a free-stream Mach number of 1.2 and at 10 deg, 20 deg, and 30 deg angle of attack alpha. At the lower angles of attack (10 and 20 deg), forced-harmonic analyses indicate that the rolling-moment coefficients provide a positive damping, which is verified by free-to-roll calculations. In contrast, at the higher angle of attack (30 deg), a forced-harmonic analysis indicates that the rolling-moment coefficient provides negative damping at the small roll amplitudes. A free-to-roll calculation for this case produces an initially divergent response, but as the amplitude of motion grows with time, the response transitions to a wing-rock type of limit cycle oscillation, which is characteristic of highly swept delta wings. This limit cycle oscillation may be actively suppressed through the use of a rate-feedback control law and antisymmetrically deflected leading-edge flaps. Descriptions of the conical Euler flow solver and the free-to roll analysis are included in this report. Results are presented that demonstrate how the systematic analysis of the forced response of the delta wing can be used to predict the stable, neutrally stable, and unstable free response of the delta wing. These results also give insight into the flow physics associated with unsteady vortical flows about delta wings undergoing forced motions and free-to-roll motions, including the active suppression of the wing-rock type phenomenon. The conical Euler methodology developed is directly extend able to three-dimensional calculations. Author (revised)

TRAILING VORTEX/FREE-SURFACE INTERACTION M.S. Thesis
Donald E. Neubert, Jr. Dec. 1992 81 p
(AD-A261654) Avail: CASI HC A05/MF A01

An investigation of the interaction of a trailing vortex with a free surface has been undertaken for the purpose of understanding the origin of scars and striations. Velocity and turbulence measurements have been carried out through the use of a Laser-Doppler-Velocimeter (LDV) for various positions of the vortex relative to the free surface. The results have shown that the vortex motion affects the free surface and is affected by it. This mutual interaction leads to the development of surface scars comprised primarily of heterostrophic vortices normal to the free surface. Furthermore, the velocity and turbulence characteristics are affected such that the vertical components of turbulence decay rapidly, and the horizontal components

stretch in the horizontal plane. The experiments have provided sufficient understanding of the physics of the phenomenon for the subsequent undertaking of the development of a predictive numerical model. DTIC

UNSTEADY AIRFOIL FLOW SOLUTIONS ON MOVING ZONAL GRIDS M.S. Thesis
Antonio M. Cricelli 17 Dec. 1992 146 p
(AD-A261925) Avail: CASI HC A07/MF A02

Investigation of subsonic and transonic steady and unsteady flowfields over airfoils is an active area of current computational and experimental research. The performance of rotary wing and fixed wing aircraft can be enhanced by taking advantage of unsteady phenomena such as dynamic lift. However, several undesirable effects have prevented designers from taking advantage of these concepts. In the past few years many advances have been made in algorithm development for the numerical solution of the Euler and the Navier Stokes equations. In this study, these new techniques are applied to the body fixed zonal grid approach. This zonal approach is more computationally efficient in solving the governing equations than previous approaches and has certain advantages over the standard single moving grid approach. The zonal grids consists of two grids: one being the inner grid which is fixed to the airfoil, and the other being the outer grid which extends to the far field or to a specified outer boundary. The inner grid is allowed to rotate with the body, while the outer grid remains fixed. The thin-layer Navier-Stokes equations are solved for the inner grid, and the Euler equations are solved for the outer grid. Communication between the two grids is accomplished by interpolating the flow quantities at the zonal interface. Solutions are obtained for flows at fixed angles of incidence, and for unsteady flows over pitching and oscillating airfoils. The computed results are in good agreement with available experimental data. DTIC

CRASHWORTHINESS OF COMPOSITE SEATS FOR CIVIL AIRCRAFT Ph.D. Thesis
V. M. Stephens 1992 283 p
Avail: Univ. Microfilms Order No. BRDX98009

Within these terms of reference, the response of the seat restraint occupant system (SROS) to impact loading was analyzed using physical (dynamic testing) and analytical (computer simulation) modeling techniques. With the increasing use of fiber-reinforced polymer composites in aircraft for weight efficiency, and the consequent appearance of composite seats, attention must be given to the crash performance of these structures. Composite structures are characterized by brittle failure with low impact energy absorption, in comparison to the collapse of metal structures which may exhibit plastic deformation prior to failure. However, using the developing technology of composite sub-structures with high specific energy absorption capability, seat structures were modified to incorporate composite load-limiting elements. The redesign process involved the compatibility of energy absorber loads with occupant dynamics to minimize injury potential, together with the alleviation of forces in the structural load path to reduce damage and preclude failure to the seat, floor track, and other components. Shortcomings of existing seat designs were assessed, and the dynamics of lap-belted occupants analyzed, including secondary head impact with the forward seat structure. The computer model created was validated against the results of dynamic tests, and then used in a parametric study of occupant dynamics. Conclusions and recommendations include guidelines relating to the future design of both metal and composite seats.

RELIABILITY ASSESSMENT AT AIRLINE INSPECTION FACILITIES. VOLUME 1: A GENERIC PROTOCOL FOR INSPECTION RELIABILITY EXPERIMENTS Final Report
Floyd Spencer, Giancarlo Borgonovi (Science Applications, Inc., Albuquerque, NM.), Dennis Roach, Don Schurman (Science Applications, Inc., Albuquerque, NM.), and Ron Smith (AEA Technology, London, England.) Mar. 1993 34 p
(DOT/FAA/CT-92/12-Vol-1) Avail: CASI HC A03/MF A01

The Aging Aircraft Nondestructive Inspection (NDI) Development and Demonstration Center (AANC) at Sandia National Laboratories is charged by the FAA to support technology transfer, technology assessment, and technology validation. A key task facing the center is to establish a consistent and systematic methodology to assess the reliability of inspections through field experiments. This task is divided into three major areas: reliability of eddy current lap splice inspections at transport aircraft maintenance facilities, reliability of inspection at commuter aircraft maintenance facilities, and reliability of inspection associated with visual inspection of aircraft structural parts. Volume 1 is the first document in a series of three describing the planning, execution, and results of an eddy current inspection field experiment. A generic protocol for inspection reliability experiments is defined. It contains an introduction to the currently accepted forms of data analysis and presentation (Probability of Detection and Receiver Operating Characteristic curves) and a discussion of the factors that may affect inspection reliability. INWARD CONTAMINANT LEAKAGE TESTS OF THE S-TRON CORPORATION EMERGENCY ESCAPE BREATHING DEVICE. PHASE 1: TESTS OF THE ORIGINAL DESIGN. PHASE 2: TESTS WITH THE REDESIGNED NECK SEAL
Bruce C. Wilcox, Jr., Harvey M. England, Jr., and Garnet A. McLean Apr. 1992 28 p
(FAA Proj. AM-B-93-PHY-152)
(DOT/FAA/AM-92/18) Avail: CASI HC A03/MF A01

At the request of S-Tron Corporation, to support their contract with the U.S. Navy, performance tests of the Emergency Escape Breathing Device (EEBD) were conducted in the Environmental Physiology Research Section contaminant leakage chamber. Sulfur hexafluoride (SF6) challenge was used to determine contaminant leakage; oxygen and carbon dioxide levels, as well as temperature readings, were also obtained. Eight successful tests were conducted with the original neck seal design first used by Scott Aviation in their Crewmember Protective Breathing Equipment, four additional tests were conducted with a proprietary new neck seal designed by S-Tron. The EEBD all performed within test limits. Author

NARROW-BODY AIRCRAFT WATER SPRAY OPTIMIZATION STUDY
Timothy R. Marker Feb. 1993 39 p Original contains color illustrations
(DOT/FAA/CT-TN93/3) Avail: CASI HC A03/MF A01

Twenty-five full-scale tests were conducted in a modified 707 narrow-body fuselage as part of an aircraft cabin water spray optimization study. The purpose was to test several spray configurations by varying the amount of water sprayed, the flow rate, and orientation of the nozzles, while keeping the fire conditions constant, in an attempt to minimize the quantity of water required to effectively suppress a postcrash aircraft fire

and improve occupant survivability. The original Safety Aircraft and Vehicles Equipment (SAVE) system was configured in the narrow-body cabin using 120 nozzles. Initially, three tests were conducted using 72, 48, and 24 gallons of water for 3-, 2-, and 1-minute spray durations, respectively. In the following series of tests, one-third of the SAVE system (40 nozzles) was configured in the area of the fire using 24, 16, and 8 gallons of water for 3-, 2-, and 1-minute spray durations, respectively. During the final series of tests, the spray system was configured in five separate sections for 'zones' with each zone carrying eight nozzles. A thermocouple was mounted at ceiling height in each zone, allowing for the activation of a particular zone when the temperature reached a predetermined value. The flow rate of the nozzles was varied as was the amount of water available during the tests. For comparison, a test was conducted without spraying water in order to establish a 'baseline.' Temperature, heat flux, smoke levels, gas concentrations, and video were continuously monitored at various locations throughout the fuselage. The optimal zoned system was more effective than the SAVE system and used only 11 percent of the water.

AIRCRAFT ACCIDENT REPORT: TOMY INTERNATIONAL, INC., D/B/A SCENIC AIR TOURS FLIGHT 22, BEECH MODEL E18S, N342E IN-FLIGHT COLLISION WITH TERRAIN, MOUNT HALEAKALA, MAUI, HAWAII, 22 APRIL 1992

2 Feb. 1993 67 p

(PB93-910401; NTSB/AAR-93/01) Avail: CASI HC A04/MF A01

This report explains Scenic Air Tours flight 22's collision with mountainous terrain on the Island of Maui, Hawaii, while the Beech E18S airplane was on an air tour flight from Hilo, Hawaii, to Honolulu, Hawaii, on 22 Apr. 1992. The safety issues discussed in the report include visual flight in instrument meteorological conditions, navigational errors, pilot preemployment qualifications and background checks, and the overall safety of the air tour industry. Recommendations concerning these issues were addressed to the Federal Aviation Administration and to Tomy International, Inc., d/b/a Scenic Air Tours. Author (revised)

A REVIEW OF CIVIL AVIATION PROPELLER-TO-PERSON ACCIDENTS: 1980-1989 Final Report

William E. Collins Jan. 1993 10 p

(AD-A260695; DOT/FAA/AM-93/2) Avail: CASI HC A02/MF A01

Various types of paint schemes on aircraft propeller and rotor blades are used to improve the visual conspicuity and attention-getting value of those blades when they are rotating. The improved conspicuity resulting from the paint schemes has the purpose of reducing the number of injuries and fatalities that might occur due to accidental contact with a rotating blade by pilots, passengers, or ground crew. The present study was undertaken to provide information regarding the circumstances surrounding such accidents in recent years and to compare those findings with the frequency and circumstances of propeller accidents during the 1965-1979 period. Computer retrievals of brief reports of all propeller accidents during the period from 1980 through 1989 were provided by the National Transportation Safety Board. Those reports were examined and analyzed in terms of type of accident, degree of injury, actions of pilots, action of passengers and ground crew, night or day, and other conditions. The computer search yielded a total of 104 reports of propeller-to-person accidents involving 106 persons. Prop-to-person accident frequency for the 1980-1989 period was notably lower than that previously reported for the 1960's and 1970's. Recent declines appear due to a combination of FAA educational efforts, economic conditions, and changes in the types of aircraft used by present aviation pilots. Irrespective of the decade under study, persons at most risk for a propeller-to-person accident are deplaning passengers and passengers attempting to assist the pilot prior to takeoff and after landing. PROAV CABLE WARNING SYSTEM (CWS) - U.S. ARMY AIRCRAFT INTEGRATION ASSESSMENT AND OCONUS FIELD EVALUATION Technical Report

Kent F. Smith and Eric C. Littleton Feb. 1993 125 p

(AD-A261233; USAATCOM-TR-93-D-1) Avail: CASI HC A06/MF A02

The PROAV Cable Warning System (CWS) is a commercially available system designed to detect the electromagnetic field generated by current-carrying wires operating at frequencies of either 50 or 60 Hz. The system is designed to alert helicopter crewmen to the presence of these wires to help prevent wire strike mishaps. As directed by the U.S. Army Aviation and Troop Command, the Aviation Applied Technology Directorate performed an aircraft integration assessment of the CWS followed by field evaluations in Germany and Korea. These field evaluations were not operational tests, since no standard or specification exists by which to judge this system. The CWS was successfully integrated on the AH-64A, AH-1F, and UH-1H aircraft. During the field evaluations, the CWS was flown a total of 207 hours by 40 different pilots. The conclusions were that the CWS was not consistent in its ability to detect wires and provide sufficient reaction time and that pilot confidence in the capabilities of the CWS was marginal to low. Also, significant aircraft integration issues remain unresolved for several U.S. Army fleet aircraft. DTIC

ILS MATHEMATICAL MODELING STUDY OF AN ILS GLIDE SLOPE PROPOSED FOR RUNWAY 19L AT THE MERIDIAN NAVAL AIR STATION, MISSISSIPPI Technical Report, Feb. 1993
James D. Rambone Apr. 1993 19 p
(Contract FAA-T0603-S)
(DOT/FAA/CT-TN93/8) Avail: CASI HC A03/MF A01

This Technical Note describes the Instrument Landing System (ILS) math modeling performed by the Federal Aviation Administration (FAA) Technical Center at the request of the Naval Command, Control, and Ocean Surveillance Center In-Service Engineering (NISE). Data are presented showing the computed performance for a glide slope proposed for runway 19L at the Meridian Naval Air Station (NAS). As requested, capture effect and null reference systems were modeled at the proposed glide slope site. The proposed site is located 783 feet back from the runway threshold and 400 feet left offset of centerline. NISE is concerned that severe terrain gradients in front of the site may adversely affect glide slope performance. Glide slope modeling was conducted using physical optics computations in the Geometric Theory of Diffraction 3D (GTD-3D) model. The GTD computations in the GTD-3D model could not accommodate a triple diffraction occurrence caused by sharp terrain gradients in front of the glide slope site. Glide slope modeling computed only the effect of the proposed terrain on glide slope performance. Preliminary modeling results for both the capture effect and null reference antennas with the proposed terrain grade indicated an out-of-tolerance excursion occurring approximately 3,000 feet in front of threshold. The first 1,000 foot section of proposed terrain grade in front of the antenna was modified slightly to eliminate this excursion in the final modeling runs. Modeled path structure and level run plots are provided for the proposed capture effect and null reference systems. Results indicate that the capture effect and null reference systems modeled with the modified proposed terrain grade should meet Category 1 path structure, linearity, and symmetry tolerances. DISCRETE RANGE CLUSTERING USING MONTE CARLO METHODS
G. B. Chatterji and B. Sridhar Mar. 1993 16 p
(RTOP 505-64-36)
(NASA-TM-104004; A-93044; NAS 1.15:104004) Avail: CASI HC A03/MF A01

For automatic obstacle avoidance guidance during rotorcraft low altitude flight, a reliable model of the nearby environment is needed. Such a model may be constructed by applying surface fitting techniques to the dense range map obtained by active sensing using radars. However, for covertness, passive sensing techniques using electro-optic sensors are desirable. As opposed to the dense range map obtained via active sensing, passive sensing algorithms produce reliable range at sparse locations, and therefore, surface fitting techniques to fill the gaps in the range measurement are not directly applicable. Both for automatic guidance and as a display for aiding the pilot, these discrete ranges need to be grouped into sets which correspond to objects in the nearby environment. The focus of this paper is on using Monte Carlo methods for clustering range points into meaningful groups. One of the aims of the paper is to explore whether simulated annealing methods offer significant advantage over the basic Monte Carlo method for this class of problems. We compare three different approaches and present application results of these algorithms to a laboratory image sequence and a helicopter flight sequence. Author

VISUAL APPROACH DATA COLLECTION AT ST. LOUIS LAMBERT FIELD (STL) Final Report, 2 Aug. - 23 Oct. 1990
James Thomas, Dominic Timoteo, and Amy E. Transue Jan. 1993 58 p
(Contract FAA-F2006-G)
(DOT/FAA/CT-TN93/2) Avail: CASI HC A04/MF A01

Data on aircraft executing simultaneous visual approaches to closely spaced parallel and intersecting runways were collected at Lambert - St. Louis International Airport (STL) between August 2 and October 23, 1990. The purpose of the data collection was to provide an accurate data base of the navigational characteristics of aircraft flying the 'fly visual' segment of the approach. Aircraft position data were collected using the in-place STL surveillance primary and secondary radars. The data were reduced and a limited analysis was performed at the Federal Aviation Administration (FAA) Technical Center by ATC Technology (ACD-340) personnel. The discussion in the Final Report concerns the accuracy of the collected position data and possible sources of error in the data collection. The reduced data were sent to the Standards Development Branch (AVN-540) for further analysis. AVN-540 will report on their findings and recommendations. Author (revised)

USING FUZZY BEHAVIORS FOR THE OUTDOOR NAVIGATION OF A CAR WITH LOW-RESOLUTION SENSORS
F. G. Pin and Y. Watanabe 1993 7 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-002428; CONF-930519-5) Avail: CASI HC A02/MF A01

Vehicle control in a priori unknown, unpredictable, and dynamic environments requires many calculational and reasoning schemes to operate on the basis of very imprecise, incomplete, or unreliable data. For such systems, in which all the uncertainties can not be engineered away, approximate reasoning may provide an alternative to the complexity and computational requirements of conventional uncertainty analysis and propagation techniques. A proposed approach using superposition of elemental fuzzy behaviors to emulate human-like qualitative reasoning schemes is first discussed. A previously developed navigation scheme implemented on custom-designed very large scale integration (VLSI) fuzzy inferencing boards for indoor navigation of a small laboratory-type robot was progressively enhanced to investigate two control modes for driving a car in a priori unknown environments on the basis of sparse and imprecise sensor data. In the first mode, the car navigates fully autonomously, while in the second mode, the system acts as a driver's aid providing the driver with linguistic (fuzzy) commands to turn left or right and speed up or slow down depending on the obstacles perceived by the sensors. Experiments with both modes of control are described in which the system uses only three acoustic range (sonar) sensor channels to perceive the environment. Simulation results as well as indoors and outdoors experiments are presented and discussed to illustrate the feasibility of outdoor navigation using fuzzy behaviors operating on possibly very inaccurate sensor data. RUNWAY VISUAL RANGE (RVR) OPERATIONAL TEST AND EVALUATION (OT&E) INTEGRATION AND OT&E OPERATIONAL TEST REPORT
William E. Brenner, Thomas C. Carty, and Joseph J. Goslin Apr. 1993 94 p
(DOT/FAA/CT-TN93/37) Avail: CASI HC A05/MF A01

The Operational Test and Evaluation (OT&E) Integration and OT&E

Operational testing of the Runway Visual Range (RVR) was conducted at the Kansas City International (MCI) Airport Traffic Control Tower (ATCT) in Kansas City, MO, and at the Kansas City (ZKC) Air Route Traffic Control Center (ARTCC) in Olathe, KA. The purpose of this test was to verify National Airspace System (NAS) integration requirements of the subsystems and the operational effectiveness of the RVR within the NAS environment. The results of OT&E testing and the results of integration and operational testing of the RVR/Maintenance Data Terminal (MDT) and RVR/Maintenance Processing System (MPS) interface requirements are addressed. Testing of the Tower Control Computer Complex (TCCC) and the Automated Surface Observation System (ASOS) NAS subsystems was deferred. It was concluded that the New Generation RVR requires corrections and/or notifications to satisfactorily meet integration and operational requirements. The New Generation RVR should not be deployed until the deployment-critical issues detailed are resolved and successfully retested. The principal concerns pertain to (1) personnel safety, (2) product integrity during an equipment failure, and (3) accuracy of the visibility product. It is further recommended that all regression testing take place using the RVR and MPS operational baseline software. Author (revised)

DESIGN CONCEPTS FOR THE DEVELOPMENT OF COOPERATIVE PROBLEM-SOLVING SYSTEMS

Philip J. Smith, Elaine McCoy (Nebraska Univ., Omaha.), Chuck Layton (Galaxy Scientific Corp., Atlanta, GA.), and Tom Bihari (Adaptive Machine Technologies, Inc., Columbia, OH.) [1992] 34 p

(Contract NCC2-615)

(NASA-CR-192708; NAS 1.26:192708) Avail: CASI HC A03/MF A01

There are many problem-solving tasks that are too complex to fully automate given the current state of technology. Nevertheless, significant improvements in overall system performance could result from the introduction of well-designed computer aids. We have been studying the development of cognitive tools for one such problem-solving task, enroute flight path planning for commercial airlines. Our goal was two-fold. First, we were developing specific systems designs to help with this important practical problem. Second, we are using this context to explore general design concepts to guide in the development of cooperative problem-solving systems. These designs concepts are described. Author (revised)

DESIGN OF A COOPERATIVE PROBLEM-SOLVING SYSTEM FOR ENROUTE FLIGHT PLANNING: AN EMPIRICAL STUDY OF ITS USE BY AIRLINE DISPATCHERS Final Report

Philip J. Smith, C. Elaine McCoy (Nebraska Univ., Omaha.), Charles Layton (Galaxy Scientific Corp., Atlanta, GA.), Judith Orasanu, Sherry Chappel, Ev Palmer, and Kevin Corker (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) 1993 69 p

(Contract NCC2-615)

(NASA-CR-192709; NAS 1.26:192709) Avail: CASI HC A04/MF A01

In a previous report, an empirical study of 30 pilots using the Flight Planning Testbed was reported. An identical experiment using the Flight Planning Testbed (FPT), except that 27 airline dispatchers were studied, is described. Five general questions were addressed in this study: (1) under what circumstances do the introduction of computer-generated suggestions (flight plans) influence the planning behavior of dispatchers (either in a beneficial or adverse manner); (2) what is the nature of such influences (i.e., how are the person's cognitive processes changed); (3) how beneficial are the general design concepts underlying FPT (use of a graphical interface, embedding graphics in a spreadsheet, etc.); (4) how effective are the specific implementation decisions made in realizing these general design concepts; and (5) how effectively do dispatchers evaluate situations requiring replanning, and how effectively do they identify appropriate solutions to these situations. THE DEPENDENT CONVERGING INSTRUMENT APPROACH PROCEDURE: AN ANALYSIS OF ITS SAFETY AND APPLICABILITY Final Report

Arthur P. Smith, III, Anand D. Mundra, David R. Barker, and Gerald A. Dorfman Nov. 1992 197 p

(Contract DTFA01-89-C-00001)

(DOE/FAA/RD-93/6) Avail: CASI HC A09/MF A03

When an airport experiences low ceiling or visibility conditions the arrival capacity is significantly reduced. This is particularly true at airports that use both their main runway and their crosswind runway in Visual Meteorological Conditions (VMC). The consequence of this is an increase in delays. A concept for continuing to conduct approaches in Instrument Meteorological Conditions (IMC) to converging runways has been proposed which calls for coordinating the approaches to the two runways such that a stagger between the aircraft is maintained. This procedure is known as Dependent Converging Instrument Approaches (DCIA). This paper develops a DCIA procedure applicable to any runway geometry. The procedure is defined and modeled to capture its safety critical aspects. From this analysis recommendations are made concerning the stagger values and other factors relevant to applying this procedure safely. Author

DESIGN OF AN AIR TRAFFIC COMPUTER SIMULATION SYSTEM TO SUPPORT INVESTIGATION OF CIVIL TILTROTOR AIRCRAFT OPERATIONS Final Report

Ralph V. Rogers 15 Mar. 1993 180 p

(Grant NAG2-625)

(NASA-CR-192920; NAS 1.26:192920) Avail: CASI HC A09/MF A02

The TATSS Project's goal was to develop a design for computer software that would support the attainment of the following objectives for the air traffic simulation model: (1) Full freedom of movement for each aircraft object in the simulation model. Each aircraft object may follow any designated flight plan or flight path necessary as required by the experiment under consideration. (2) Object position precision up to +/- 3 meters vertically and +/- 15 meters horizontally. (3) Aircraft maneuvering in three space with the object position precision identified above. (4) Air traffic control operations and procedures. (5) Radar, communication, navaid, and landing aid performance. (6) Weather. (7) Ground obstructions and terrain. (8) Detection and recording of separation violations. (9) Measures of performance including deviations from flight plans, air space violations, air traffic control messages per aircraft, and traditional temporal based measures. Author

PILOTED SIMULATION OF AN AIR-GROUND PROFILE NEGOTIATION PROCESS IN A TIME-BASED AIR TRAFFIC CONTROL ENVIRONMENT

David H. Williams and Steven M. Green (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) Apr. 1993 45 p

(RTOP 505-64-13-01)

(NASA-TM-107748; NAS 1.15:107748) Avail: CASI HC A03/MF A01

Historically, development of airborne flight management systems (FMS) and ground-based air traffic control (ATC) systems has tended to focus on different objectives with little consideration for operational integration. A joint program, between NASA's Ames Research Center (Ames) and Langley Research Center (Langley), is underway to investigate the issues of, and develop systems for, the integration of ATC and airborne automation systems. A simulation study was conducted to evaluate a profile negotiation process (PNP) between the Center/TRACON Automation System (CTAS) and an aircraft equipped with a four-dimensional flight management system (4D FMS). Prototype procedures were developed to support the functional implementation of this process. The PNP was designed to provide an arrival trajectory solution which satisfies the separation requirements of ATC while remaining as close as possible to the aircraft's preferred trajectory. Results from the experiment indicate the potential for successful incorporation of aircraft-preferred arrival trajectories in the CTAS automation environment. Fuel savings on the order of 2 percent to 8 percent, compared to fuel required for the baseline CTAS arrival speed strategy, were achieved in the test scenarios. The data link procedures and clearances developed for this experiment, while providing the necessary functionality, were found to be operationally unacceptable to the pilots. In particular, additional pilot control and understanding of the proposed aircraft-preferred trajectory, and a simplified clearance procedure were cited as necessary for operational implementation of the concept. SYSTEM FOR CALIBRATING A GYRO NAVIGATOR Patent
John S. Stambaugh, inventor (to Navy) 24 Nov. 1992 4 p Filed 31 Mar. 1989
(AD-D015668; US-Patent-5,166,882; US-Patent-Appl-SN-349381; US-Patent-Class-364-453) Avail: US Patent and Trademark Office

The present invention relates to a system for calibrating translation equations of a gyro navigator of a submarine. A value of velocity and a value of position of the submarine are produced by using values of acceleration sensed by accelerometers in the navigation gyro. The value of velocity and position are produced with the aid of the translation equations. This value of velocity and value of position are compared with a value of velocity and a value position as produced by a more accurate and independent source. A comparison is made with the aid of Kalman filter. Any difference obtained during a comparison is used in order to calibrate the translation equations of the gyro navigator. DTIC

REPAIR, EVALUATION, MAINTENANCE, AND REHABILITATION RESEARCH PROGRAM. CONTINUOUS DEFORMATION MONITORING SYSTEM (CDMS) Final Report
Carl A. Lanigan Dec. 1992 52 p
(AD-A261833; WES/TR/SL-REMR-CS-39) Avail: CASI HC A04/MF A01

The US Army Topographic Engineering Center (TEC) has developed an automated deformation monitoring technology known as the Continuous Deformation Monitoring System (CDMS). The CDMS is capable of computing structural deformation using the Global Positioning System (GPS) survey technology while operating in a continuous fashion over time. A network of two personal computers control GPS survey equipment and process the satellite data gathered to compute apparent structural deformation up to 24 times a day without the presence of an operator. Structural monitoring can take place at the project site or at a distant office. Performance testing by TEC has determined deformation measurement precision in the subcentimeter range. The CDMS was installed at Dworshak Dam in northern Idaho and tracked the upstream movement of the dam while undergoing reservoir drawdown. DTIC

CONVERSION OF THE CTA, INC., EN ROUTE OPERATIONS CONCEPTS DATABASE INTO A FORMAL SENTENCE OUTLINE JOB TASK TAXONOMY Final Report
Mark D. Rodgers and Gena K. Drechsler Jan. 1993 77 p
(AD-A261410; DOT/FAA/AM-93/1) Avail: CASI HC A05/MF A01

FAA Air Traffic Control Operations Concepts Volume VI: ARTCC-Host En Route Controllers (1990) developed by CTA, Inc., a technical description of the duties of an En Route air traffic control specialist (ATCS), formatted in User Interface Language, was restructured into a hierarchical formal sentence outline. To ensure that none of the meaning associated with a task or task element was lost during the conversion, the revised document was reviewed by subject matter experts (SME's) consisting of five groups of six En Route controllers and a quality assurance subject matter expert. SME's looked for words, phrases, or acronyms not commonly used by En Route controllers, and illogical sequencing of duties described in the document. Appropriate suggestions for change were implemented into the document before the next review. Five-hundred seventy-five changes were made to the document, with only two of these changes made during the final review, confirming that an improved document resulted from the research. The restructured document is intended to assist in the identification of tasks not performed or performed incorrectly during the commission of an operational error. However, an easily understood, detailed description of duties performed by an En Route ATCS has potential not only for use by researchers interested in En Route ATCS tasks, but also by quality assurance investigation teams and training personnel. IMAGE-BASED RANGING AND GUIDANCE FOR ROTORCRAFT
P. K. A. Menon Dec. 1991 80 p
(Contract NCC2-575)
(NASA-CR-177608; A-93061; NAS 1.26:177608) Avail: CASI HC A05/MF A01

This report documents the research carried out under NASA Cooperative Agreement No. NCC2-575 during the period Oct. 1988 - Dec. 1991. Primary emphasis of this effort was on the development of vision based navigation methods for rotorcraft nap-of-the-earth flight regime. A family of field-based ranging algorithms were developed during this research period. These ranging schemes are capable of handling both stereo and motion image sequences, and permits both translational and rotational camera motion. The algorithms require minimal computational effort and appear to be implementable in real time. A series of papers were presented on these ranging schemes, some of which are included in this report. A small part of the research effort was expended on synthesizing a rotorcraft guidance law that directly uses the vision-based ranging data. This work is discussed in the last section. Author

GENERAL AVIATION AIRCRAFT: NORMAL ACCELERATION DATA ANALYSIS AND COLLECTION PROJECT Final Report
James E. Locke, Howard W. Smith, Edward A. Gabriel, and Thomas DeFlore Feb. 1993 341 p Prepared in cooperation with Wichita State Univ., KS
(DOT/FAA/CT-91/20; KU-FRL-926-1) Avail: CASI HC A15/MF A03

This report contains the analysis and condensation of repeated flight loads obtained from 77 airplanes that participated in the NASA Velocity Gravity Height (VGH) General Aviation Program. In addition, the load spectra for 98 airplanes in the NASA VGH data base are presented as plotted and tabulated data. Curve fit equations are listed for the original data and for extrapolation, which was used in the statistical analysis. Airspeed, normal load factor, and altitude were recorded continuously during flight. The load factor data were separated into gust and maneuver normal accelerations. The reduced data are presented as cumulative number of occurrences per nautical mile versus acceleration fraction (incremental normal acceleration divided by incremental limit load factor). For statistical analysis, the airplanes were grouped into seven single and twin-engine operational usage groups. The mean (weighted by flight time), weighted mean--plus one, two, and three standard deviation spectra, and the 90 percent probability/95 percent confidence spectra were determined for each operational usage group and for several of the groups combined. An estimate of the scatter associated

with groups having small sample size was determined by computing a pooled variance and pooled standard deviation. The resulting load spectra are to be used for wing fatigue test or safe-life estimation. The Federal Aviation Administration's plans for further study using the results of this report are discussed. The final objective of this effort is to produce a revised fatigue evaluation report for small and commuter airplane certification under Part 23 of the Federal Aviation Regulations. Author (revised)

AERODYNAMIC DESIGN AND SYNTHESIS OF THE OBLIQUE FLYING WING SUPERSONIC TRANSPORT Ph.D. Thesis
Alexander Jacobus M. VanderVelden 1992 310 p
Avail: Univ. Microfilms Order No. DA9234183

The performance of an oblique flying wing supersonic transport was investigated in this study and its economics were compared with those of conventional transports. Aerodynamics, structures, propulsion, environmental impact, (sonic boom, ozone, noise) and economy were analyzed for a given mission, subject to environmental constraints from Mach 0.8 to Mach 2.0. Twenty variables represented the aircraft geometry, engine characteristics, and mission. These variables were optimized simultaneously for the aircraft families as a function of Mach number, payload, and range. The globally optimized oblique flying wing was designed in detail with a new design method and analyzed with CFD codes. The wing did not only achieve the low drag predicted by the synthesis method but was trimmable over its entire flight envelope. Results showed oblique flying wings with payloads over 400 passengers to be superior for all missions considered. At supersonic speeds operating costs half that of delta-wing transports were achieved. The improvements were attributable to the higher lift-to-drag ratios as well as the beneficial effect of span loading on the structural weight. Dissert. Abstr.

GENERIC HYPERSONIC VEHICLE PERFORMANCE MODEL Interim Task Report
Frank R. Chavez and David K. Schmidt Apr. 1993 32 p
(Grant NAG1-1341)
(NASA-CR-192953; NAS 1.26:192953; ARC-93-3) Avail: CASI HC A03/MF A01

An integrated computational model of a generic hypersonic vehicle was developed for the purpose of determining the vehicle's performance characteristics, which include the lift, drag, thrust, and moment acting on the vehicle at specified altitude, flight condition, and vehicular configuration. The lift, drag, thrust, and moment are developed for the body fixed coordinate system. These forces and moments arise from both aerodynamic and propulsive sources. SCRAMjet engine performance characteristics, such as fuel flow rate, can also be determined. The vehicle is assumed to be a lifting body with a single aerodynamic control surface. The body shape and control surface location are arbitrary and must be defined. The aerodynamics are calculated using either 2-dimensional Newtonian or modified Newtonian theory and approximate high-Mach-number Prandtl-Meyer expansion theory. Skin-friction drag was also accounted for. The skin-friction drag coefficient is a function of the freestream Mach number. The data for the skin-friction drag coefficient values were taken from NASA Technical Memorandum 102610. The modeling of the vehicle's SCRAMjet engine is based on quasi 1-dimensional gas dynamics for the engine diffuser, nozzle, and the combustor with heat addition. The engine has three variable inputs for control: the engine inlet diffuser area ratio, the total temperature rise through the combustor due to combustion of the fuel, and the engine internal expansion nozzle area ratio. The pressure distribution over the vehicle's lower aft body surface, which acts as an external nozzle, is calculated using a combination of quasi 1-dimensional gas dynamic theory and Newtonian or modified Newtonian theory. The exhaust plume shape is determined by matching the pressure inside the plume, calculated from the gas dynamic equations, with the freestream pressure, calculated from Newtonian or Modified Newtonian theory. In this manner, the pressure distribution along the vehicle after body expansion surface is then determined. The aerodynamic modeling, the engine modeling, and the exhaust plume analysis are described in more detail. A description of the computer code used to perform the above calculations is given and an input/output example is then given. The computer code is available on a Macintosh floppy disk. INTEGRATED AERODYNAMIC-STRUCTURAL WING DESIGN OPTIMIZATION Ph.D. Thesis
Eric Robert Unger 1992 101 p
Avail: Univ. Microfilms Order No. DA9220650

Several procedures for the simultaneous aerodynamic-structural design optimization of aircraft wings are investigated. These procedures include efficient methods for optimization and sensitivity calculations that are applied to two specific design examples. The first is a subsonic transport aircraft with a composite forward-swept wing. The aerodynamic modeling for this case is provided by vortex-lattice theory and the structural model initially utilizes finite-element analyses. Even with efficient sensitivity methods, the approximate optimization problem still requires a large computational effort. To reduce this cost, a variable-complexity model for the structural analyses is introduced. First, an algebraic equation model for wing weight is used in the optimization procedure to obtain an aerodynamic design that approximately accounts for the effects of wing geometry on wing weight. Then this design is refined by simultaneous aerodynamic-structural optimization based on the finite-element analysis. The net effect of this dual structural model is a substantial reduction in optimization costs. The second example is the wing design of a supersonic High-Speed Civil Transport (HSCT). For this case, the simple wing-weight equations for structures are retained. For the aerodynamics, a variable-complexity model was introduced with the complex models provided by volumetric wave drag analysis and panel methods. In addition, simple algebraic models for wave and drag use to lift provide inexpensive approximations during most of the optimization cycles. With the minimization of the costly complex sensitivity calculations, a reduction in optimization costs is realized. Dissert. Abstr.

A PRELIMINARY SIZING METHOD FOR UNMANNED AIRCRAFT USING MULTI-VARIATE OPTIMISATION Ph.D. Thesis
A. Turnbull 1990 383 p
Avail: Univ. Microfilms Order No. BRDX98006

The project was carried out, initially, under sponsorship from RAE Farnborough, the object being to obtain a design 'tool' to aid the initial project design work done on turbojet propelled unmanned aircraft. Hence, a sizing method for any unmanned air vehicle configuration with turbojet propulsion, using methods compatible with RAE multi-variate optimization techniques, evolved. The scope of the research was extended to include both turbojet and piston propulsion systems. The range of vehicle configuration is wide, with a choice of internally or externally mounted turbojet engines, forward tractor type or rear pusher type piston engines; conventional flying surfaces or twin boom, twin fin type configurations. The internal fuselage layout is user-defined and has numerous possibilities. The aircraft synthesis uses standard mass and drag estimations, where applicable, for the airframe and vehicle systems, such as fuselage, wing, propulsion, electrics, and recovery systems. The synthesized vehicle is assumed to fly a user-specified mission profile with the performance and fuel requirements for each leg of the sortie being calculated. The mission profile can consist of a maximum of seven legs: climb, cruise, loiter, acceleration, high speed dash, maneuver, and return. The total fuel consumption, along with the fuel reserves are calculated to give the total overall vehicle mass. The design synthesis can be used as a stand-alone program or with the optimization package, RQPMIN. During the latter the vehicle mass is optimized with respect to specified configuration parameters while having to satisfy user-specified constraints (both geometric and performance related). A detailed output is produced, giving the initial and final vehicle configurations; including component masses, total geometric values and mission performance details. The optimization program details, such as constraint and independent variable values are also given. Dissert. Abstr.

APPLICATION OF FINITE-STATE INFLOW TO FLAP-LAG-TORSION DAMPING IN HOVER Ph.D. Thesis
Donizeti deAndrade 1992 204 p
Avail: Univ. Microfilms Order No. DA9303157

The aeroelastic stability of helicopter rotors in hovering flight is investigated by a coupled set of generalized dynamic wake equations and hybrid equations of motion for an elastic blade cantilevered in bending and having a torsional root spring to model pitch-link flexibility. The

generalized dynamic wake model employed is based on an induced flow distribution expanded in a set of harmonic and radial shape functions, including undetermined time dependent coefficients as aerodynamic states. The flow is described by a system of first-order, ordinary differential equations in time, for which the pressure distribution at the rotor disk is expressed as a summation of the discrete loadings on each blade, accounting simultaneously for a finite number of blades and overall rotor effects. The nonlinear blade equations are simplified by the assumption of uniform blade mass and stiffness; and then they are reduced to nonlinear differential equations by Galerkin's method. Inflow and blade equations are matched in a way to establish a standard eigen-analysis for the stability of small motions about blade equilibrium and steady-state inflow. The coefficient matrices in the eigenproblem depend on the numerical solution of blade equilibrium and steady-state inflow nonlinear algebraic equations. The model has been applied to a two-bladed, untwisted, stiff inplane hingeless small scale rotor with torsionally soft blades, including a blade root offset, and hub designed to permit variation in precone, blade droop, pitch control stiffness, and blade pitch angle. Numerical results show that three-dimensional tip relief effects within the nonuniform steady-state inflow are significant to predict steady-state aerodynamic loads and blade deflections. The eigenvalue results confirmed the importance of unsteady, three-dimensional aerodynamics in predicting lead-lag damping, by means of correlations with unsteady three-dimensional panel theory and with experiments. Eigenvector analysis correlations reinforced qualitative and quantitative shortcomings associated with quasi-steady two-dimensional aerodynamic theory for aeroelastic applications in hover. Overall results from this research set the present finite-state methodology as a suitable tool to handle helicopter integrated dynamics. This is chiefly due to elimination of time-marching and moving block analysis inherent to previous approaches to the same problem, implying in substantial savings in computer memory and time, with no essential loss of accuracy. Dissert. Abstr.

N93-25526 Stanford Univ., CA.
STRUCTURAL AND AERODYNAMIC OPTIMIZATION OF JOINED-WING AIRCRAFT Ph.D. Thesis
John Waldemar Gallman 1992 258 p
Avail: Univ. Microfilms Order No. DA9234097

The joined wing is an innovative aircraft configuration with a rear wing that is attached near the top of the vertical tail and sweeps forward to join the trailing edge of the forward wing. This study evaluates the performance of joined-wing aircraft and demonstrates the use of numerical optimization in aircraft design. Initially, a parametric design study that considered a single cruise condition indicated an 11 percent savings in trimmed drag for a joined-wing with the same lifting surface area and 23 percent longer wing span than a conventional configuration. These results encouraged further study of the joined-wing concept and motivated the development of a computer program that uses numerical optimization to design both joined-wing and conventional configurations. This design program uses a vortex-lattice model of all aircraft components to calculate aerodynamic forces and a beam model of the lifting-surface structure to calculate wing and tail weight. Weight estimation depends on a fully-stressed design algorithm that includes a constraint on buckling and a correlation with a statistically based method for total lifting-surface weight. This fully-stressed sizing routine produced joined-wing structures that are nearly identical to minimum-weight structures designed using numerical optimization. A variety of 'optimum' joined-wing and conventional aircraft designs were compared on the basis of direct operating cost, gross weight, and cruise drag. Maximum lift and tail buckling were identified as critical joined-wing design issues. The addition of a buckling constraint was shown to decrease the optimum joined-wing space by 8 percent and increase direct operating cost by 4 percent. Although aeroelasticity and dynamic stability were neglected during the design study, separate analyses showed that the optimum configurations have sufficient damping for good handling qualities and flutter speeds that are well above the design dive speed. The most promising joined-wing designs have a joint location at about 70 percent of the wing semispan, a fuel tank in the tail to trim, and a flap spanning 70 percent of the wing. These designs are shown to cost 3 percent more to operate than a conventional configuration designed for the same medium-range mission. Dissert. Abstr.

AEROELASTIC RESPONSE AND AEROMECHANICAL STABILITY OF HELICOPTERS WITH ELASTICALLY COUPLED COMPOSITE ROTOR BLADES Ph.D. Thesis
Edward C. Smith 1992 453 p
Avail: Univ. Microfilms Order No. DA9304398

A comprehensive formulation was developed to study the effects of elastically coupled composite helicopter rotor blades on aeroelastic response, blade and hub loads, rotor aeroelastic stability, and rotor-fuselage aeromechanical stability. Both hover and forward flight conditions are addressed, and the aeromechanical stability analysis includes both air and ground resonance phenomenon. A new analysis was formulated to model the laminated composite box-beam blade spar. The box-beam analysis includes the nonclassical structural effects of transverse shear, torsion-related out-of-plane warping, and two-dimensional ply elasticity. Elastic couplings are introduced through the anisotropy of the plies in the composite spar. For the aeroelastic and aeromechanical analysis, the blade is idealized as an elastic beam undergoing moderate deflections in flap and lag bending, elastic torsion, elastic axial deformation, and flap and lag transverse shear. A nineteen d.o.f. shear flexible beam element is introduced for the composite rotor blades. The structural model is validated by correlation with experimental data and finite element solutions for static deflections of elastically coupled graphite-epoxy composite box-beams. The quantitative importance of the nonclassical structural effects is also investigated. The free vibration analysis is validated by correlation with experimental data and finite element results for the in vacuo rotating natural frequencies of the composite box-beams. The aeromechanical stability analysis is correlated against experimental data for a model hingeless rotor-body configuration. Results indicate that elastic couplings introduced through the composite blade spar have a powerful effect on both shaft-fixed blade stability and rotor-body aeromechanical stability. The torsional response is also significantly affected by the composite couplings. Influence of composite couplings on blade and hub loads was measurable, but less pronounced. Dissert. Abstr.

N93-25538 Georgia Inst. of Tech., Atlanta.
AN INTEGRATED FINITE-STATE MODEL FOR ROTOR DEFORMATION, NONLINEAR AIRLOADS, INFLOW, AND TRIM Ph.D. Thesis
Walter Martin Stumpf 1992 236 p
Avail: Univ. Microfilms Order No. DA9303147

Existing models for forward flight rotor aeroelastic loads suffer from a number of deficiencies. These models often use crude aerodynamics coupled with sophisticated blade equations, require excessive computation, contain modules that must be solved sequentially rather than simultaneously, or contain hidden states or a large number of states. The aeroelastic model described here addresses these deficiencies. It is a time-domain, state-space aeroelastic model of a rotor in forward flight. The model computes trim, airloads, rotor shaft loads and the instantaneous inflow distribution. All components of the model are expressed as ordinary differential equations, which are solved by integrating the system in time until a periodic solution is reached. The states have physical significance and, since there are a finite number of them, Floquet theory may be applied. The aerodynamic and structural models are of a comparable level of sophistication and are strongly coupled. The section airloads are described by a classical thin airfoil theory, which treats the wake contribution as a external forcing function. The airloads are modified to reflect the presence of dynamic stall using the semi-empirical ONERA dynamic stall model. The wake contribution is computed using the Peters generalized dynamic inflow theory, which is based on a series solution of the potential-flow equation. The Hodges and Dowell elastic blade equations are approximated using the Galerkin-Ritz method. Trim is found using an automatic controller, also written as a set of ordinary-differential equations. When the number of shape functions and aerodynamic control points are chosen to include dynamics up to a frequency of four per rev., the model including inflow, stall, blade deformations and trim, is defined by about 50 state variables. A trimmed solution requires between 10 and 40 revolutions to trim, and costing about four minutes of CPU time per ten revolutions (on a VAX 6440). The model response has been validated using flight test data from the SA349 helicopter. The blade motions and aerodynamic normal forces predicted by the model agreed fairly well with the measured values, but the pitching moment predictions were less successful. Dissert. Abstr.

A COMPUTATIONAL AERODYNAMIC DESIGN OPTIMIZATION METHOD USING SENSITIVITY ANALYSIS Ph.D. Thesis
Mohamed El-Amin Eleshaky 1992 235 p
Avail: Univ. Microfilms Order No. DA9230207

A new and efficient procedure for aerodynamic shape optimization is presented. The salient lineaments of this procedure are: (1) using a discrete sensitivity analysis approach to determine analytically the aerodynamic sensitivity coefficients; (2) obtaining the flowfield solution either by a computational fluid dynamics (CFD) analysis or, alternatively, by a flowfield extrapolation method which is based on a truncated Taylor's series; (3) defining the aerodynamic shape in such a way that it is not restricted to any class of surfaces and the optimizer automatically shapes the aerodynamic configuration to any arbitrary geometry; and (4) requiring no expertise other than that needed for formulating the optimization problem in question. This procedure is successfully demonstrated on different aerodynamic optimization problems. In one of the optimization problems, the ramp shape of a scram jet nozzle-afterbody configuration is optimized to yield a maximum thrust force coefficient. However, prior to its design optimization, a CFD capability for the mixing of two-dimensional, viscous, multispecies flows has been developed in order to gain a detailed understanding of the complex flowfield features of the scram jet nozzle-afterbody configuration. It is shown that heavier exhaust mixture (simulated by a Freon-Argon mixture) undergoes gas dynamic expansion at a smaller rate than does lighter 'air' exhaust flow. In the sensitivity analysis approach, both Euler and thin-layer Navier-Stokes equations are used. Their discretized equations are solved using an implicit, upwind-biased, finite-volume scheme. The van Leer flux-vector splitting is used in the discretization of the pressure and convective terms. The direct and iterative solution methods, which are deemed most applicable to the large linear systems of algebraic equations arising in the sensitivity approach, are investigated with regards to their accuracies, computational time, and computer memory requirements. These methods are shown to be feasible only for small two-dimensional problems. Due to the prohibitively high memory requirements, they become impractical for large two-dimensional problems and inapplicable for any of the three-dimensional problems. To alleviate this limitation, a new scheme based on domain decomposition principles has been developed and is called the Sensitivity Analysis Domain-Decomposition (SADD) scheme. Dissert. Abstr.

TRAJECTORY OPTIMIZATION FOR THE NATIONAL AEROSPACE PLANE Semiannual Report, 13 Jun. - 12 Dec. 1992
Ping Lu Jan. 1993 10 p
(Grant NAG1-1255)
(NASA-CR-192954; NAS 1.26:192954) Avail: CASI HC A02/MF A01

While continuing the application of the inverse dynamics approach in obtaining the optimal numerical solutions, the research during the past six months has been focused on the formulation and derivation of closed-form solutions for constrained hypersonic flight trajectories. Since it was found in the research of the first year that a dominant portion of the optimal ascent trajectory of the aerospace plane is constrained by dynamic pressure and heating constraints, the application of the analytical solutions significantly enhances the efficiency in trajectory optimization, provides a better insight to understanding of the trajectory and conceivably has great potential in guidance of the vehicle. Work of this period has been reported in four technical papers. Two of the papers were presented in the AIAA Guidance, Navigation, and Control Conference (Hilton Head, SC, August, 1992) and Fourth International Aerospace Planes Conference (Orlando, FL, December, 1992). The other two papers have been accepted for publication by Journal of Guidance, Control, and Dynamics, and will appear in 1993. This report briefly summarizes the work done in the past six months and work currently underway. Derived from text

AN APPROACH TO CONFIGURATION DESIGN SYNTHESIS OF SUBSONIC TRANSPORT AIRCRAFT USING ARTIFICIAL INTELLIGENCE TECHNIQUES Ph.D. Thesis
H. M. Pasaribu 1991 272 p
Avail: Univ. Microfilms Order No. BRDX97987

This thesis outlines a computer system developed to tackle the configuration design synthesis of subsonic transport aircraft. The system provides an interactive design environment which combines the reasoning process of the aircraft configuration definition and the numerical analyses that lie behind the reasoning. The system applies artificial intelligence (AI) techniques to the configuration analysis. This gives the system the capability to reason with the configuration choices. The system is built in modules, with each module being clearly separated to deal with a complete analysis in a specific aspect of design. The integration of the modules is done through an intelligent interface and a common database. The interface also incorporates AI techniques in deciding the sequence of execution of the modules and the processing of the input/output data for a particular module. The interface permits the sharing of information among the modules and supports modularity and flexibility of the system for future development. Since each module is independent, it can be easily modified or replaced without disturbing the balance of the system. An extensive library of application programs is included in the engineering analysis module which enable detailed analysis to be performed. The system is equipped with a simplified database management and a special purpose graphics module which is extensively used for the presentation of the output. The system has been validated and tested. It can handle both propeller driven and jet engined aircraft. An example of the case studies is presented. The improvement of the system for future development is also considered. These include the extension of the knowledge base for dealing with problems in other modules, the enhancement of the application programs in the engineering module, and a possible interface with an established Computer Aided Drafting (CAD) system. Dissert. Abstr.

N93-25701 Rensselaer Polytechnic Inst., Troy, NY.
DESIGN AND ANALYSIS OF CURVED COMPOSITE COMPONENTS FOR ROTORCRAFT FUSELAGE FRAMES Ph.D. Thesis
Ann W. Peck 1992 238 p
Avail: Univ. Microfilms Order No. DA9302698

An investigation in the design and analysis of curved composite components for rotorcraft fuselage frames was conducted. Using a strength of material based approach, analytical expressions were developed to predict the flange and web stress resultants in curved beams made of anisotropic materials. Two parameters, which include flange and web geometric and material stiffness effects, have been identified that characterize the flange stress redistributions due to curling. After validation of the analytical solutions using a finite element model, a parameter study was performed to examine the effects material anisotropy and cross-sectional configuration have on the flange curving behavior. It has been found that the flange and web laminates have a significant effect on the internal stress distributions. Reducing flange curling reduces the amount of flange axial load redistribution but increases the maximum curling moment. An increase of the web bending stiffness increases the overall bending stiffness and flange efficiency, but also increases the flange root curling moment and the web bending moment in the C- and box cross-sectonal configurations. At some point, an increase in the web bending stiffness diminishes the overall load carrying capability as the web becomes the critical element. It appears to be difficult to utilize material anisotropy to improve the overall load carrying capability. Formal optimization techniques were used to investigate the maximum load carrying capability of curved composite beams. The overall driving design factor was found to be flange curling. To maximize overall load carrying capability in curved composite beams with fixed-length flanges, the overall bending stiffness is maximized by minimizing web thicknesses and moving structural material out towards the flanges and flange curling minimized by minimizing flange lengths, increasing flange thicknesses, minimizing web thicknesses in the C- and box beams, placing predominantly 0 degree and 90 degree fibers in the flange laminates with 0 degree fibers on the interior and 90 degree fibers on the outside, and placing predominantly 0 degree fibers in the web laminates of the C- and box configurations. The optimum cross-sectional configuration is dependent on chosen quantities, such as flange lengths, beam mass. For fixed-length flanges, no clear optimum cross-section was found. Dissert. Abstr.

N93-25704 Cranfield Inst. of Tech., Bedford (England).
ASTOVL COMBAT AIRCRAFT DESIGN SYNTHESIS AND OPTIMIZATION Ph.D. Thesis
N. Kehayas 1992 293 p
Avail: Univ. Microfilms Order No. BRDX98001

This thesis presents the development of a Baseline Configuration for

an Advanced Short Take-Off and Vertical Landing (ASTOVL) Combat Aircraft, the Design Synthesis and coding of this Baseline Configuration (Code VERTI), the interfacing of the Design Synthesis Code VERTI with the Optimizer code RQPMIN and the optimization of the Baseline Configuration. The background and the objectives of this Research Program are initially examined. The evaluation of the ASTOVL Combat Aircraft Baseline Configuration is then described, including all the problems, assumptions, choices and compromises that led to the specific configuration. The development of the Design Synthesis and the Code VERTI then follow, where the methodology used, the techniques adopted and the code operation are explained. A full description of the Design Synthesis is included as an appendix. Finally, the interfacing of Code VERTI with the optimizer RQPMIN and the optimization of the Baseline Configuration are presented. The problems and difficulties of the RQPMIN operation are thoroughly discussed. The RQPMIN-VERTI Code is used to optimize the initial Baseline Configuration and an optimization example is provided in appendix form. The optimized Baseline Configuration is partly validated against two ASTOVL combat aircraft designs. In addition to the optimization with the aircraft empty mass as objective function, a search for a better objective function is attempted. Dissert. Abstr.

N93-25719 Rensselaer Polytechnic Inst., Troy, NY.
STRUCTURAL DYNAMIC ANALYSIS OF BEARINGLESS ROTOR BLADE Ph.D. Thesis
Wuying Chiang 1992 261 p
Avail: Univ. Microfilms Order No. DA9236209

Conventional articulated helicopter rotor systems typically have mechanical hinges, dampers and bearings in the hub to relieve high blade root moments and to ensure dynamic stability. This hardware operates in a high stress field and experiences large cyclic and centrifugal loads. These devices require continuous inspection and frequent maintenance. In addition, they can significantly degrade the reliability of the rotor system. In order to improve helicopter reliability, reduce maintenance, and potentially improve rotor hub aerodynamic characteristics, the helicopter researchers have developed the hingeless and bearingless rotor by taking advantage of recent advancements in materials technology. The unique structural features of bearingless rotors calls for the development of design and modeling methodologies for laminated composite flex-structures. Indeed, the flex-structure should be flexible enough to replace the flap, lead-lag, and feathering bearings, while maintaining high strength and stiffness in the axial direction. Laminated composite materials are a material of choice for such an application. Chordwise deformations, transitional zones between different cross-sections and localized compressive stresses are all likely to be present in the flex-structure, rendering the validity of a beam model questionable. In this research an anisotropic shallow shell model is developed that accommodates transverse shearing deformations and arbitrarily large displacements and rotations. However, strains are assumed to remain small. Two kinematic models are developed in this research: the first model uses two rotation parameters to locate the direction of the normal to the shell's mid-plane while the second one uses a rotation tensor which is composed of three parameters. The latter model, which has an in-plane rotation degree-of-freedom, allows for an automatic compatibility of the shell model with other three-dimensional structural models. A shell model is validated by comparing its predictions with several benchmark problems which include static and dynamic, linear and nonlinear, as well as isotropic and anisotropic conditions. The performance of the in-plane rotation degree-of-freedom of the shell model is tested also by solving some special configurations. In actual helicopter rotor blade problems, the shell model of the flex-structure is shown to give very different results when compared to beam models. The lead-lag and torsion modes are strongly affected, whereas flapping modes seem to be less affected. A study was also carried out to simulate a tail rotor system; the pitch actuator force is found to vary significantly when shell or beam models are used. Dissert. Abstr.

AIRCRAFT ELECTRICAL AND ENVIRONMENTAL SYSTEMS, AFSCs 452X5, 454X5, AND 454X6
Jan. 1993 71 p
(AD-A261213) Avail: CASI HC A04/MF A01

This is a report of an occupational survey of the Electrical and Environmental Systems career ladders conducted by the Occupational Analysis Flight, USAFOMS. The Headquarters Air Training Command (ATC) Aircraft/ Munitions maintenance Training Division requested this survey to project, plan, and develop Career Development Courses (CDC), STS's, and training for these career ladders due to the Rivet Workforce restructing of AFSC 423X0--Aircraft Electrical Systems and AFSC 423X1--Aircraft Environmental Systems. The last surveys pertaining to these career ladders were published in Feb. 1984 (AFSC 423X1) and Feb. 1985 (AFSC 423X0). The merger of the Electrical and Environmental, Strategic Electrical and Environmental, and Airlift Electrical and Environmental. Members of all these career ladders participated in this survey. In Jun. 1992, a U and TW decided to merge the three ladders into a single Aircraft Electrical and Environmental Systems career ladder (AFSC 452X5), effective Apr. 1993. DTIC

PERFORMANCE-BASED TESTING AND SUCCESS IN NAVAL ADVANCED FLIGHT TRAINING Interim Report
David J. Blower Nov. 1992 35 p
(NR Proj. M00-96)
(AD-A260838; NAMRL-1378) Avail: CASI HC A03/MF A01

Roughly 5 percent of student naval aviators fail the advanced phase of flight training. At this stage of training, the Navy has spent between $300,000 and $1,000,000 per student. Any reduction in this attrition rate through prior screening would be of great economic benefit to the Navy. Computer-based performance tests developed at the Naval Aerospace Medical Research Laboratory were assessed to determine whether they could augment the present medical screening standards and thereby help identify potential failures in advanced flight training. A weak statistical relationship exists between a dual-task performance test, accession source, college major, an aptitude test, and success in advanced flight training. Discriminant analysis was employed to find a linear composite score of these variables that could be used to classify a student as a probable pass or fail in advanced flight training. For example, the model presented in this report reduced failures by 50 percent at the cost of rejecting roughly 20 percent of those students who eventually passed. A Bayesian analysis of the success rate parameter showed that this particular model significantly improved the present selection system. DTIC

INFORMATION REQUIREMENTS ANALYSES FOR TRANSATMOSPHERIC VEHICLES Final Report, Jul. 1991 - Jun. 1992
Gilbert G. Kuperman Jun. 1992 218 p
(Contract F33615-89-C-0532)
(AD-A261189; AL-TR-1992-0082) Avail: CASI HC A10/MF A03

An information requirements analysis was performed as the initial step in the design of crew system concept for future transatmospheric vehicles (TAVs). A knowledge acquisition, synthesis, and representation process was conducted. A baseline system description was prepared. Concept Maps were generated. A mission event sequence was developed. System architecture depictions were generated. Measures of effectiveness and performance were documented. DTIC

AEW AIRCRAFT DESIGN M.S. Thesis
Michael J. Wagner Dec. 1992 114 p
(AD-A261800) Avail: CASI HC A06/MF A02

The aging E-2C fleet is expected to be retired by the year 2015. In order to provide Airborne Early Warning (AEW) for the battle group during the transitional years and beyond, the design of a replacement aircraft must begin soon. In order to conform with present day economic realities, one possible configuration is a new airframe using the radar system and rotodome which currently operates on the E-2C. Other likely requirements for a new AEW aircraft includes a high-speed dash (M=0.7-0.85) capability, an extended mission time (up to 7.5 hours), turbofan engines, and an aircrew ejection system. The results of this design effort includes an investigation of a possible configuration and the aerodynamics involved. Performance, stability and control characteristics are also discussed briefly. Finally, a qualitative analysis of the use of the E-2C's radar system on a new airframe will be presented. DTIC

EFFECT OF IMAGE UPDATE RATE ON MOVING-TARGET IDENTIFICATION RANGE Final Report, Jan. 1991 - Jun. 1992
Julie M. Lindholm and Elizabeth L. Martin Jan. 1993 24 p
(Contract F33615-90-C-0005)
(AD-A261562; AL-TR-1992-0172) Avail: CASI HC A03/MF A01

In prior research, moving-form perception tended to be nonveridical when the update rate of an image generator (IG) was less than the refresh rate of the display device. In this experiment, the effect of update rate on the range at which pilots could identify computer-generated representations of moving aircraft was examined. For a 60-Hz interlaced display, identification range was greater for a 60-Hz image update rate than for a 30-Hz update rate. This effect held for two views of three pairs of aircraft moving at two different velocities. These results suggest that image update rate is an important design parameter for simulators intended to support air-to-air combat training. To maximize the range at which a moving target can be identified, the update rate of the IG should equal the refresh rate of the display device. DTIC

SUPERSONIC AEROELASTIC INSTABILITY RESULTS FOR A NASP-LIKE WING MODEL
Stanley R. Cole, James R. Florance, Lee B. Thomason, Charles V. Spain (Lockheed Engineering and Sciences Co., Hampton, VA.), and Ellen P. Bullock (Lockheed Engineering and Sciences Co., Hampton, VA.) Apr. 1993 12 p Presented at the AIAA 34th SDM Conference, Hampton, VA, 19-23 Apr. 1993
(RTOP 763-23-41)
(NASA-TM-107739; NAS 1.15:107739) Avail: CASI HC A03/MF A01

An experimental study and an analytical study have been conducted to examine static divergence for hypersonic-vehicle wing models at supersonic conditions. A supersonic test in the Langley Unitary Plan Wind Tunnel facility was conducted for two wind-tunnel models. These models were nearly identical with the exception of airfoil shape. One model had a four-percent maximum thickness airfoil and the other model had an eight-percent maximum thickness airfoil. The wing models had low-aspect ratios and highly swept leading edges. The all-movable wing models were supported by a single-pivot mechanism along the wing root. For both of the wind-tunnel models, configuration changes could be made in the wing-pivot location along the wing root and in the wing-pivot pitch stiffness. Three divergence conditions were measured for the four-percent thick airfoil model in the Mach number range of 2.6 to 3.6 and one divergence condition was measured for the eight-percent thick airfoil model at a Mach number of 2.9. Analytical divergence calculations were made for comparison with experimental results and to evaluate the parametric effects of wing-pivot stiffness, wing-pivot location, and airfoil thickness variations. These analyses showed that decreasing airfoil thickness, moving the wing-pivot location upstream, or increasing the pitch-pivot stiffness have the beneficial effect of increasing the divergence dynamic pressures. The calculations predicted the trend of experimental divergence dynamic pressure with Mach number accurately; however, the calculations were approximately 25 percent conservative with respect to dynamic pressure. EVALUATION OF ADVANCED DISPLAYS FOR ENGINE MONITORING AND CONTROL Final Report
L. G. Summers (McDonnell-Douglas Automation Co., Long Beach, CA.) Mar. 1993 71 p
(Contract NAS1-18028; RTOP 505-64-13-12)
(NASA-CR-191418; NAS 1.26:191418; MDC-92K0374) Avail: CASI HC A04/MF A01

The relative effectiveness of two advanced display concepts for monitoring engine performance for commercial transport aircraft was studied. The concepts were the Engine Monitoring and Control System (EMACS) display developed by NASA Langley and a display by exception design. Both of these concepts were based on the philosophy of providing information that is directly related to the pilot's task. Both concepts used a normalized thrust display. In addition, EMACS used column deviation indicators; i.e., the difference between the actual parameter value and the value predicted by an engine model, for engine health monitoring; while the Display by Exception displayed the engine parameters if the automated system detected a difference between the actual and the predicted values. The results showed that the advanced display concepts had shorter detection and response times. There were no differences in any of the results between manual and auto throttles. There were no effects upon perceived workload or performance on the primary flight task. The majority of pilots preferred the advanced displays and thought they were operationally acceptable. Certification of these concepts depends on the validation of the engine model. Recommendations are made to improve both the EMACS and the display by exception display formats. Author (revised)

Subcontractor (Southwest Research Institute) describes the hardware and software comprising the Flight Instrument Package (FIP), a collection of transducers and electronic components that measure primary flight motion and position parameters and generate digital data representing those parameters. Pitch angle, bank angle, altitude, vertical velocity, airspeed, heading, and angle of attack are the main quantities digitized and relayed to a data port for processing into various displays of aircraft state. The FIP developed as part of this task was used in a Beech Queen Air aircraft to drive the Acoustic Orientation Instrument, which provides the pilot with an auditory display of aircraft bank, airspeed, vertical velocity, and other parameters as necessary. (AD-A260752; AL-TR-1992-0160) Avail: CASI HC A19/MF A04

Subcontractor (Southwest Research Institute) provides engineering data and system software description for the Acoustic Orientation Instrument (AOI), which they developed for inflight testing. The overall scheme of operation of the system involves inputting a frame of scaled flight data (airspeed, bank angle, vertical velocity, etc.) from the Flight Instrument Package (FIP) over an RS232 serial link to the AOI, conversion of the flight data to corresponding output voltage waveforms by the AOI, and delivery of those outputs to stereo headphones to generate an auditory display of the flight parameters of interest. This report constitutes an operation and maintenance manual for the AOI, including system programming in the FORTH computer language. DTIC

TECHNICAL OPERATING REPORT ON THE DATA INTEGRATION AND COLLECTION ENVIRONMENT (DICE) INSTRUMENTATION SYSTEM DESIGN Interim Report
Sep. 1992 68 p
(Contract F44606-89-D-0040)
(AD-A261105; WL-TR-93-1001) Avail: CASI HC A04/MF A01

This Technical Operating Report (TOR) provides the top level and intermediate level hardware design of the Data Integration and Collection Environment (DICE) system. The design objectives are: (1) provide the capability to configure and control the collection of specific APG-63 radar and weapons system data; (2) provide for the collection of any and all D-bus, PMUX, CCMUX, and PACS communication data; (3) provide a data

storage capability which exceeds two hours; (4) provide a mechanism for replaying the recorded data to the laboratory instrumentation data reduction and analysis system (IDRAS) in a time phased manner; (5) identify sources for dual compatible militarized and commercial off-the-shelf components; (6) provide prototype road map for the system's production; and (7) provide for filtered data capture processing. A brief description of the overall objectives of this system is presented. The applicable documents, both Government and non-Government, for the DICE system are identified. The instrumentation system design is described. DTIC

FUEL INJECTOR: AIR SWIRL CHARACTERIZATION AEROTHERMAL MODELING, PHASE 2, VOLUME 1 Final Report

M. Nikjooy (General Motors Corp., Indianapolis, IN.), H. C. Mongia (General Motors Corp., Indianapolis, IN.), V. G. McDonell (California Univ., Irvine.), and G. S. Samuelsen (California Univ., Irvine.) Mar. 1993 407 p

(Contract NAS3-24350; RTOP 505-62-52)

(NASA-CR-189193; E-7593; NAS 1.26:189193) Avail: CASI HC A18/MF A04

A well integrated experimental/analytical investigation was conducted to provide benchmark quality relevant to a prefilming type airblast fuel nozzle and its interaction with the combustor dome air swirler. The experimental investigation included a systematic study of both single-phase flows that involved single and twin co-axial jets with and without swirl. A two-component Phase Doppler Particle Analyzer (PDPA) was used to document the interaction of single and co-axial air jets with glass beads that simulate nonevaporating spray and simultaneously avoid the complexities associated with fuel atomization processes and attendant issues about the specification of relevant boundary conditions. The interaction of jets with methanol spray produced by practical airblast nozzle was also documented in the spatial domain of practical interest. Model assessment activities included the use of three turbulence models (k-epsilon, algebraic second moment (ASM), and differential second moment (DSM)) for the carrier phase, deterministic or stochastic Lagrangian treatment of the dispersed phase, and advanced numerical schemes. Although qualitatively good comparison with data was obtained for most of the cases investigated, the model deficiencies in regard to modeled dissipation rate transport equation, single length scale, pressure-strain correlation, and other critical closure issues need to be resolved before one can achieve the degree of accuracy required to analytically design combustion systems. (NASA-TM-106042; E-7620; NAS 1.15:106042) Avail: CASI HC A03/MF A01

The application of advanced control concepts to airbreathing engines may yield significant improvements in aircraft/engine performance and operability. Accordingly, the NASA Lewis Research Center has conducted screening studies of advanced control concepts for airbreathing engines to determine their potential impact on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed concepts was formulated by NASA and industry. These concepts were evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation, three target aircraft/engine combinations were considered: a military high performance fighter mission, a high speed civil transport mission, and a civil tiltrotor mission. Each of the advanced control concepts considered in the study were defined and described. The concept's potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts were also determined. Finally, the concepts were ranked with respect to the target aircraft/engine missions. Author

EXPERIMENTAL PERFORMANCE OF A VENTRAL NOZZLE WITH PITCH AND YAW VECTORING CAPABILITY FOR SSTOVL AIRCRAFT

Barbara S. Esker and Jack G. McArdle Apr. 1993 12 p Presented at the Aerospace Atlantic Conference, Dayton, OH, 20-23 Apr. 1993; sponsored by SAE

(RTOP 505-68-32)

(NASA-TM-106054; E-7648; NAS 1.15:106054) Avail: CASI HC A03/MF A01

Aircraft with supersonic, short takeoff, and vertical landing capability were proposed to replace some of the current high-performance aircraft. Several of these configurations use a ventral nozzle in the lower fuselage, aft of the center of gravity, for lift or pitch control. Internal vanes canted at 20 deg were added to a swivel-type ventral nozzle and tested at tailpipe-to-ambient pressure ratios up to 5.0 on the Powered Lift Facility at NASA LeRC. The addition of sets of four and seven vanes decreased the discharge coefficient by at least 6 percent and did not affect the thrust coefficient. Side force produced by the nozzle with vanes was 14 percent or more of the vertical force. In addition, this side force caused only a small loss in vertical force in comparison to the nozzle without vanes. The net thrust force was 8 deg from the vertical for four vanes and 10.5 deg for seven. Author (revised)

MEASUREMENTS AND COMPUTATIONS OF EXTERNAL HEAT TRANSFER AND FILM COOKING IN TURBINES

S. P. Harasgama, C. D. Burton, and K. S. Chana 24 Feb. 1992 14 p Presented at the 10th International Symposium on Air Breathing Engines, Nottingham, England, 1-6 Sep. 1991 Previously announced in IAA as A91-56238

(RAE-TM-P-1223; BR310269) Copyright Avail: CASI HC A03/MF A01

A review of recent work on turbine heat transfer performed at the RAE (Pyestock) is presented. The work covers the effects of secondary flows on turbine nozzle guide vane heat transfer with and without film cooling. It is shown that the heat load to the platforms (end walls) are significantly affected by the secondary flow action. The platform film cooling data has been well correlated with flat plate single row film cooling data to within +11 percent. A three-dimensional Navier-Stokes computational study of the effects of turbine inlet temperature distortion on the thermo-fluid mechanics within a rotating blade passage is given. It is shown that the temperature distortion is modified within the rotor blade and can lead to increased pressure side and over tip heat transfer. Author

DESIGN AND PERFORMANCE OF NOZZLE-LESS VOLUTE CASINGS FOR INWARD FLOW RADIAL TURBINES Ph.D. Thesis
Hassam O. Owarish 1989 148 p
Avail: Univ. Microfilms Order No. BRDX97192

Inward Flow Radial Turbines are widely used in industry, particularly in turbochargers, small gas turbine engines, and aircraft starters and air conditioning systems. The turbine stage comprises essentially a stator or casing and a rotor. In feeding the flow into the turbine rotor, a well designed casing should achieve the following objectives: (1) acceleration of the working fluid and direct it at a specific angle in to the rotor; (2) production of congruent velocity triangles around the inlet periphery of the rotor; and (3) achieve (1) and (2) with a minimum loss of total pressure. The efficiency of Inward Flow Radial Turbines fitted with vaneless casings is lower than that of similar turbines fitted with the more expensive casings using guide vanes or nozzles. The difference is attributed to the more controlled flow occurring in the vaned casing. It is believed that such a flow can be achieved in the vaneless casing if the state of the art related to design methods is improved. In the past, all design methods have been based on the assumption of one-dimensional free vortex flow. The author's contribution has been in the development of a novel method of flow analysis and design of single-entry vaneless casing. This method is based on two-dimensional flow which takes the shape of the cross-section into account. In this method, the casing is divided into a number of segments which are sub-divided into a number of control volumes. By considering the changes in momenta in the tangential and radial directions across each control volume, together with the equations of energy, state, and continuity of mass, the changes in flow properties are computed. The flow model and the design method were constructed as FORTRAN computer programs that require only the operating conditions, that is mass flow rate, total pressure, and total temperature of entry as input, and make use of numerical methods to solve the equations. The relationships between geometrical dimensions at a fixed set of operating conditions, and the relationships between geometrical dimensions and operating conditions given by this design method have also been studied. OPTIMIZED SCRAMJET ENGINE INTEGRATION ON A WAVERIDER AIRFRAME Ph.D. Thesis
Mary Kae Lockwood ONeill 1992 205 p
Avail: Univ. Microfilms Order No. DA9304373

One of the keys to the success of air breathing hypersonic vehicles is the effective integration of the air breathing engine with the airframe. The practicality of integrating waveriders with hydrogen fueled scramjet engines is investigated. This is the first study to develop waveriders specifically for the purpose of scramjet integration. A method was developed, and a corresponding computer code was written, to optimize the waverider and scramjet together to take full advantage of the benefits of the waverider while providing the scramjet with the properties required for effective combustion. Two classes of air breathing hypersonic vehicle concepts, one for primarily cruise missions and the other for accelerator type missions, are presented. Cruise configurations are optimized for the product of specific impulse and lift-to-drag ratio while matching lift to weight, corrected for centrifugal force, and thrust to drag at some equivalence ratio. Accelerator configurations are optimized for effective specific impulse while matching lift to weight, corrected for centrifugal force, at an equivalence ratio of one. Waveriders are derived from conical flow-fields, the combustor is modeled with quasi 1-D flow and the inlet and nozzle are modeled with 2-D planar flow. The results of an optimization include the fore body shape, inlet shape, engine location along the length of the vehicle, engine span, vehicle volume, and the approximate values for effective specific impulse, L/D, specific impulse, and center of pressure for the optimized configuration. The results indicate that waveriders are promising configurations for hypersonic vehicles. A 60 m Mach 8 vehicle flying at 50.3 km altitude, optimized for cruise, has an L/D of 4.7, an Isp of 2786 sec, and a 2258 cu m volume. A 60 m Mach 10 cruise vehicle, flying at an altitude of 55.1 km has an L/D of 3.5, an Isp of 2417 sec, and a volume of 2686 cu m. A 60 m Mach 14 accelerator, flying at an altitude of 36.9 km has an Isp(sub eff) of 531 sec and a 3902 cu m volume. A 60 m Mach 10 accelerator, flying at an altitude of 31.8 m has an Isp(sup eff) of 1512 sec and a 4155 cu m volume. Dissert. Abstr.

THREE-DIMENSIONAL FLOW IN RADIAL TURBOMACHINERY AND ITS IMPACT ON DESIGN Final Report, Sep. 1985 - Oct. 1992
Choon S. Tan and William Hawthorne May 1993 15 p
(Grant NAG3-772)
(NASA-CR-192957; NAS 1.26:192957) Avail: CASI HC A03/MF A01

In the two papers on the 'Theory of Blade Design for Large Deflections' published in 1984, a new inverse design technique was presented for designing the shape of turbomachinery blades in three-dimensional flow. The technique involves the determination of the blade profile from the specification of a distribution of the product of the radius and the pitched averaged tangential velocity (i.e., r bar-V(sub theta), the mean swirl schedule) within the bladed region. This is in contrast to the conventional inverse design technique for turbomachinery blading in two dimensional flow in which the blade surface pressure or velocity distribution is specified and the blade profile determined as a result; this is feasible in two-dimensional flow because the streamlines along the blade surfaces are known a priori. However, in three-dimensional flow, the stream surface is free to deform within the blade passage so that the streamlines on the blade surfaces are not known a priori; thus it is difficult and not so useful to prescribe the blade surface pressure or velocity distribution and determine the resulting blade profile. It therefore seems logical to prescribe the swirl schedule within the bladed region for designing a turbomachinery blade profile in three-dimensional flow. Furthermore, specifying r bar-V(sub theta) has the following advantages: (1) it is related to the circulation around the blade (i.e., it is an aerodynamic quantity); (2) the work done or extracted is approximately proportional to the overall change in r bar-V(sub theta) across a given blade row (Euler turbine equation); and (3) the rate of change of r bar-V(sub theta) along the mean streamline at the blade is related to the pressure jump across the blade and therefore the blade loading. Since the publications of those two papers, the technique has been applied to the design of a low speed as well as a high speed radial inflow turbine (for turbocharger applications) both of which showed definite improvements in performance over that of wheels of conventional designs, the design study of a high pressure ratio radial inflow turbine with and without splitter blades. GAS TURBINE SYSTEM SIMULATION: AN OBJECT-ORIENTED APPROACH
Colin K. Drummond, Gregory J. Follen, and Charles W. Putt Apr. 1993 14 p Presented at the 23rd Annual Pittsburgh Conference on Modeling and Simulation, Pittsburgh, PA, 30 Apr. - 1 May 1992; sponsored by the Univ. of Pittsburgh, IEEE, ISA, and SCS
(RTOP 505-62-51)
(NASA-TM-106044; E-7632; NAS 1.15:106044) Avail: CASI HC A03/MF A01

A prototype gas turbine engine simulation has been developed that offers a generalized framework for the simulation of engines subject to steady-state and transient operating conditions. The prototype is in preliminary form, but it successfully demonstrates the viability of an object-oriented approach for generalized simulation applications. Although object oriented programming languages are-relative to FORTRAN-somewhat austere, it is proposed that gas turbine simulations of an interdisciplinary nature will benefit significantly in terms of code reliability, maintainability, and manageability. This report elucidates specific gas turbine simulation obstacles that an object-oriented framework can overcome and describes

the opportunity for interdisciplinary simulation that the approach offers.

NUMERICAL MODELLING OF VISCOUS TURBOMACHINERY FLOWS WITH A PRESSURE CORRECTION METHOD Ph.D. Thesis
A. Tourlidakis 1992 369 p
Avail: Univ. Microfilms Order No. BRDX97988

A fully elliptic computational method for the analysis of steady viscous flow in high speed subsonic centrifugal compressor impellers with tip leakage, is presented. A generalized curvilinear, non-orthogonal grid is utilized and the time-averaged Navier-Stokes equations are transformed and expressed in a fully conservative form. The discretization of the governing equations is performed through finite volume integration. The solution procedure employs a non-staggered variable arrangement and a SIMPLE based method for coupling the velocity and pressure fields. The turbulence effects are simulated with the use of the k-epsilon model, modified to account for rotation and streamline curvature, and the near-wall viscous phenomena are modeled through the wall function method. The numerical model is implemented for the flow prediction in a series of two and three dimensional test cases. Incompressible flow predictions in two-dimensional cascades and three-dimensional ducting systems with different geometrical features and inlet conditions are initially performed and the numerical results are compared against available experimental data. The final objective of the present study is achieved through the comparative study of the predictions obtained against the results of Eckardt's experimental investigation of the viscous compressible flow in a high speed radial impeller operating at design condition and in a backswept impeller at design and off-design conditions. In addition, the flow is simulated in the passages of the Rolls Royce GEM impeller which was tested at Cranfield at design and off-design flow rates. A jet/wake pattern was discerned in all the simulated centrifugal compressor cases and a good overall agreement was achieved with the measured wake formation and development; and, encouraging results were obtained on the evolution of the secondary flows. The tip leakage effects influenced the loss distribution, the size and the location of the wake flow pattern at the rotor exit. The effects of the flow mass rate on the detailed flow pattern and on the compressor performance have been well represented. In certain cases, the quality of the present predictions is an improvement over that obtained by other state-of-the-art Navier-Stokes solvers. In conclusion, the developed finite volume flow model has captured a large number of complex flow phenomena encountered in the tested impellers and is expected to provide a useful aerodynamic analysis tool for stationary or rotating, axial or radial turbomachinery components.

SIMULATION OF AIRCRAFT GAS TURBINE ENGINE Ph.D. Thesis
Ibrahim H. Ismail 1991 260 p
Avail: Univ. Microfilms Order No. BRDX97196

This thesis describes GTES (gas turbine engine simulation) a digital computer program that simulates the design and off-design performance of aircraft gas turbine engines. The program can also perform test analysis for the individual components of these engines. A general description of gas turbine engines and their applications is described in Chapter 1. A review of the previous work (papers and reports) related to this area is covered in Chapter 2. A theoretical background of aerothermodynamics and gas dynamics of gas turbine engines, also the components performance characteristics and performance of the complete engine is discussed in Chapter 3. A general description of the program philosophy and the modules control procedure is explained in Chapter 4. The modelling procedure for each component and for the complete engine is introduced in Chapter 5. A validity of the simulation program results in comparing with available engine test data and the discussion of the simulation result is shown in Chapter 6. The concluding remarks which are derived from this research and the recommendations for further work are included in Chapter 7. The main parts of this program are, data entry, components performance and complete engine run. The main features of this program are that, it has been written for IBM compatible micro computers and is modular in its approach, at the same time losses in the stationary components have been considered in this work. In author's view this approach is novel and it should make a significant contribution to the simulation work.

THE EFFECTS OF REACTION ON AXIAL COMPRESSOR PERFORMANCE Ph.D. Thesis
C. D. Farmakalides 1992 312 p
Avail: Univ. Microfilms Order No. BRDX97979

The present study examined the effects of design point choice of degree of reaction on axial flow compressor performance. The study, which has been partly sponsored by a market leader in industrial compressors, has been born from the need to improve on the compressor's stable operating range preferably at no loss of efficiency. Two kinds of blading, one of 100 percent and one of 80 percent reaction, were designed for mass flow and work coefficients of .6 and .4 respectively. The 80 percent reaction blading was manufactured and together with an existing 50 percent reaction blading has been tested on CIT's three stage axial flow research facility. Tests carried out, using the 50 percent and 80 percent reaction blading, involved measurements of performance over the stable range of operation and included traverse investigation carried out at two flow conditions. Three builds were tested using each blading with stator stagger settings of design, design +10 degrees and design -10 degrees. For the six builds tested, performance measurements were carried out with particular attention given to the operating range and maximum efficiency. Mid pitch radial and mid span circumferential traverse investigation, carried out for flow conditions near optimum and stall, examined the variation of aerodynamic parameters with flow rate and helped to validate methods used for compressor blading design and performance analysis. Analysis of the experimental data was conducted using three performance prediction methods: (1) a simple method based on generalized correlations; (2) a through-flow method STRCUR based on Denton's stream-line curvature calculation technique and applied only to the two builds with design stator stagger settings and for flow conditions near optimum point; and (3) a stream-line curvature method AXCHAR which is based on the solution of a simplified radial equilibrium equation. The experimental findings of this study indicated that high reaction blading can result in some stall margin and stable operating range improvement at no loss of maximum efficiency. Such trends were indicated even when the level of reaction was increased by a stator restaggering process. The analysis carried out indicated that: (1) a simple methods for obtaining the stage characteristic curves are suitable for preliminary analysis; (2) the through-flow code STRCUR can predict the internal flow field provided secondary flow losses are accounted for; and (3) the code AXCHAR is a useful tool for the prediction of stage characteristics and also provides valuable information regarding radial distributions of aerodynamic parameters at flow conditions varying from choke to stall. The analysis identified areas for improvement in the correlations used for stall point and off-design deviation angle prediction.

RADIAL INFLOW TURBINE STUDY Final Report, 1 Mar. - 30 Jun. 1992
S. Hamid and R. L. Elder Jul. 1992 120 p
(Contract DAJA45-89-C-0006)
(AD-A260767; CIT/REF-06-769(E); RTD-5824-AN-01) Avail: CASI HC A06/MF A02

Small radial inflow turbines have various applications in industry and are successfully being used as a major component of gas turbines and turbochargers. The performance of the turbine is of great importance for the success of these systems. Although the design of radial inflow turbines has improved in the last few years, the detailed aerodynamic study of these components still needs considerable attention. Better understanding of the flow processes involved in these machines will provide a good basis for the design of improved components and for this purpose a joint research program has been undertaken by Cranfield, the U.S. Army Research Office and Turbomach (San Diego). The main objective of the study was to investigate the flow processes involved in the radial inflow turbine using experimental methods. The work presented in this report describes the various steps undertaken to perform these studies together with results. The project involved two phases, the first measurements downstream of the rotor and the second measurements between the nozzle guide vanes and rotor inlet. The scope of the study was limited to two man years during which considerable success was achieved in obtaining the desired measurement but more time to further reduce this data and to compare

with computational results, which was outside the scope of the present study, would have been advantageous. The studies using laser anemometry undertaken downstream of the turbine rotor indicated a swirling flow with a region of counter-rotating flow in the centre. A cobra probe was used to compare with the laser anemometry results. Both measuring techniques show similar trends of flow velocity and flow angle at various running conditions. DTIC

ROTATING RAKE DESIGN FOR UNIQUE MEASUREMENT OF FAN-GENERATED SPINNING ACOUSTIC MODES

Kevin E. Konno and Clifford R. Hausmann Apr. 1993 23 p

(RTOP 535-03-01)

(NASA-TM-105946; E-7814; NAS 1.15:105946) Avail: CASI HC A03/MF A01

In light of the current emphasis on noise reduction in subsonic aircraft design, NASA has been actively studying the source of and propagation of noise generated by subsonic fan engines. NASA/LeRC has developed and tested a unique method of accurately measuring these spinning acoustic modes generated by an experimental fan. This mode measuring method is based on the use of a rotating microphone rake. Testing was conducted in the 9 x 15 Low-speed Wind Tunnel. The rotating rake was tested with the Advanced Ducted Propeller (ADP) model. This memorandum discusses the design and performance of the motor/drive system for the fan-synchronized rotating acoustic rake. This novel motor/drive design approach is now being adapted for additional acoustic mode studies in new test rigs as baseline data for the future design of active noise control for subsonic fan engines. Included in this memorandum are the research requirements, motor/drive specifications, test performance results, and a description of the controls and software involved. Author (revised)

FLOW CONTROL OF LOW HEAT LOAD TURBINE AIRFOILS Final Report, Jul. 1987 - Feb. 1991

A. H. Epstein, G. R. Guenette, T. D. Stone, and W. J. Stentoe 28 Feb. 1992 312 p

(Contract F33615-87-C-2729)

(AD-A260941; WL-TR-91-2079) Avail: CASI HC A14/MF A03

The goal of this work was to examine how the heat load to turbines may be reduced by aerodynamic design. The effort consisted of three separate investigations: (1) determination of the effect of small grooves in the flow direction (riblets) on heat transfer, (2) an investigation of the role of inviscid flow aerodynamics on heat load, and (3) examination of the measurement technology required to assess heat transfer and aerodynamic performance in a short duration turbine test facility. For the first effort, a low turbulence, constant wall temperature wind tunnel was constructed with one wall containing riblets. Measurements indicated a maximum of 5 percent reduction in heat transfer and 7 percent in skin friction drag. In the second effort, an integral technique was developed to predict laminar flow heat transfer and drag losses for a two-dimensional airfoil. The integral method was incorporated into the ISES inverse design code and comparisons were made to existing calculational methods and experimental data. For the third effort, errors associated with heat transfer and aerodynamic performance measurements in short duration (isothermal) test facilities were found to be small but not negligible. It is shown that these errors can be estimated to sufficient accuracy so that data from short duration facilities will have equal or better accuracy than that from conventional turbine rigs. DTIC

THE BLADE CURVING EFFECTS IN A TURBINE STATOR CASCADE WITH LOW ASPECT RATIO

Wang Zhongqi and Han Wanjin 21 Jan. 1993 16 p Transl. into ENGLISH from Jnl. of Engineering Thermophysics (China), v. 11, no. 3, Aug. 1990 p 255-262

(Contract F33657-84-D-0165)

(AD-A261063; FASTC-ID(RS)T-0312-92) Avail: CASI HC A03/MF A01

In a low speed plane cascade tunnel, the experiments for the cascades equipped with conventional straight blades, linear inclined blades and curvilinear blades were carried out. Through the comparisons of the experimental results, the improving effects of blade curving on the flow fields are discussed. The experimental results show that using curvilinear blades in the rectangular turbine stator cascades with low aspect ratio can reduce the overall flow loss by 30-40%. DTIC

ACTIVE STABILIZATION OF AEROMECHANICAL SYSTEMS Final Technical Report, 1 Nov. 1989 - 31 Oct. 1992

Alan H. Epstein, Edward M. Greitzer, John Dugundji, Vincent H. Garnier, and Daniel L. Gysling 5 Jan. 1993 161 p

(Grant AF-AFOSR-0059-90)

(AD-A261366; AFOSR-93-0142TR) Avail: CASI HC A08/MF A02

This report details the work on the active control of surge and stall in gas turbine engines. The use of small amplitude waves predicted by theory as stall precursors were tested with experimental data. The nonlinear behavior of such waves was shown to explain much of the data in the literature. This theory was used to design an active stabilization system for rotating stall which was tested on both a single-stage and a three-stage axial compressor, increasing the stable operating range of the single-stage compressor by 25%. The dynamics of the three-stage compressor were shown to match closely with theory. The open-loop forced response characteristics of the compressors were measured and methodology developed in which this data was used to design the compressor control system. The models then developed were used to evaluate alternate control strategies. Engineering of the structural dynamics of the compression system was also shown to be successful in damping rotating stall and surge. DTIC

PARTICULATE EMISSIONS FROM GAS TURBINE ENGINES

1 Feb. 1992 150 p Revised

(AD-A261374; AESO-2-90-REV) Avail: CASI HC A07/MF A02

The Aircraft Environmental Support Office is one of four specialty offices within the Naval Environmental Protection Support Service which offers technical support to the naval community. The Aircraft Environmental Support Office is primarily responsible for the management and distribution of emissions data for gaseous and particulate air pollutants from aircraft engines. This handbook, Particulate Emissions From Aircraft Engines, is a summary of particulate emissions data collected by the Aircraft Environmental Support Office since 1981. This handbook is intended for environmental personnel at military installations who must provide regulatory agencies with information about particulate matter emitted from their engine test facilities. Most users will find that the sections on visible emissions and particulate emission rates and concentrations contain all the information normally required to make permit applications, emission inventories and related regulatory documents. Also, the section on particle size distributions is appropriate to design applications. Together these sections provide a comprehensive treatment of particulate emissions from aircraft engines. DTIC

PREDICTION OF FORCES AND MOMENTS FOR HYPERSONIC FLIGHT VEHICLE CONTROL EFFECTORS Final Report

Mark D. Maughmer, Lyle N. Long, Neal Guilmette, and Peter Pagano 3 May 1993 70 p

(Grant NAG1-849)

(NASA-CR-193033; NAS 1.26:193033) Avail: CASI HC A04/MF A01

This research project includes three distinct phases. For completeness, all three phases of the work are briefly described in this report. The goal was to develop methods of predicting flight control forces and moments

for hypersonic vehicles which could be used in a preliminary design environment. The first phase included a preliminary assessment of subsonic/supersonic panel methods and hypersonic local flow inclination methods for such predictions. While these findings clearly indicated the usefulness of such methods for conceptual design activities, deficiencies exist in some areas. Thus, a second phase of research was conducted in which a better understanding was sought for the reasons behind the successes and failures of the methods considered, particularly for the cases at hypersonic Mach numbers. This second phase involved using computational fluid dynamics methods to examine the flow fields in detail. Through these detailed predictions, the deficiencies in the simple surface inclination methods were determined. In the third phase of this work, an improvement to the surface inclination methods was developed. This used a novel method for including viscous effects by modifying the geometry to include the viscous/shock layer. Author (revised)

ROBUST NONLINEAR CONTROL OF VECTORED THRUST AIRCRAFT
John C. Doyle, Richard Murray, and John Morris 31 May 1993 44 p
(Grant NAG2-792)
(NASA-CR-192727; NAS 1.26:192727) Avail: CASI HC A03/MF A01

An interdisciplinary program in robust control for nonlinear systems with applications to a variety of engineering problems is outlined. Major emphasis will be placed on flight control, with both experimental and analytical studies. This program builds on recent new results in control theory for stability, stabilization, robust stability, robust performance, synthesis, and model reduction in a unified framework using Linear Fractional Transformations (LFT's), Linear Matrix Inequalities (LMI's), and the structured singular value micron. Most of these new advances have been accomplished by the Caltech controls group independently or in collaboration with researchers in other institutions. These recent results offer a new and remarkably unified framework for all aspects of robust control, but what is particularly important for this program is that they also have important implications for system identification and control of nonlinear systems. This combines well with Caltech's expertise in nonlinear control theory, both in geometric methods and methods for systems with constraints and saturations. Author

AEROSPACE VEHICLE MODEL SIMPLIFICATION FOR FEEDBACK CONTROL Ph.D. Thesis
Brett Alan Newman 1992 214 p
Avail: Univ. Microfilms Order No. DA9301354

This dissertation addresses three distinct topics within the broader scope of aerospace vehicle model simplification for feedback control. These topics include order reduction criteria for feedback control, frequency weighted internally balanced order reduction, and symbolic factoring of transfer function polynomials. Before ever reducing the dynamic order of a model located within a feedback system, it is critical to understand which dynamic characteristics are crucial to preserve so that the reduced order closed-loop system will exhibit those key characteristics similar to the higher order closed-loop system. Based upon closed-loop stability and stability robustness requirements, order reduction criteria are derived, specifically for sequential loop closure settings. The weighted, internally balanced truncation technique delivers a reduced model that is accurate in a frequency range specified by the user. As yet, however, no existing a priori error bound has been obtained for the technique. Building upon a previous attempt, an error analysis is presented which gives support to the technique. Also, a new reduction technique, which combines weighted, balanced coordinates with residualization, is presented. The functional dependence of linear system poles and zeros upon the basic system parameters appearing in the governing differential equations offers insight into the causes for key dynamic characteristics. A Taylor series based approach is offered to generate approximate symbolic expressions for the poles and zeros in terms of the basic system parameters. Dissert. Abstr.

CONTROL OF NONLINEAR SYSTEMS UNDER INPUT CONSTRAINTS WITH APPLICATIONS TO FLIGHT CONTROL Ph.D. Thesis
Albert W. Lee 1992 137 p
Avail: Univ. Microfilms Order No. DA9304980

In this dissertation, stability and performance enhancement of systems under input constraints are examined. A simultaneous Lyapunov stability problem is solved to examine sufficient conditions for global asymptotic stability of linear plants with input constraints. The sufficient conditions are then extended to systems whose nonlinearities are globally Lipschitz. For performance enhancement, a new design method is introduced to minimize performance degradation resulting from control saturation. Although the theories for input-output linearization and sliding control are well developed, they are not particularly well suited for systems with input constraints. An approximate input-output linearization method is presented to enhance performance of the closed loop systems under input constraints. This method is demonstrated on a longitudinal flight control problem to significantly improve the closed-loop performance. Dissert. Abstr.

CONTROL AND OPTIMIZATION OF AIRCRAFT TRAJECTORIES Ph.D. Thesis
Younis Sharif Daoud 1991 207 p
Avail: Univ. Microfilms Order No. BRDX97200

The thesis describes a multi-disciplinary program of research which covers three fields of study, namely: control systems engineering; flight dynamics; and numerical optimization. However the main thrust of the research is in the area of control system engineering. A real time computer algorithm has been developed to control and optimize the trajectory of an aircraft during a maneuver along a path in the vertical plane. The equations of motion of a craft represented by a point mass model moving in the vertical plane are known from flight dynamics. These equations are used to define the trajectory and an optimization routine is used to minimize the time of flight along this trajectory. The real time control algorithm controls the movement of the point mass along this trajectory with path and terminal constraints. The optimization utilizes an adjoint control transformation algorithm for solving the two point boundary value problem that describes the optimal control. The initial values of the adjoint multipliers are related non-linearly to the initial values of the controls by which the system is operated. Since the system is practical and initial values are chosen by an iterative optimization scheme, the optimization is solved without the sensitivity problems of the classical method. The optimization yields a reference family of optimal controls; a near optimal guidance law that transfers the aircraft to the vicinity of the reference family is then described. The control commands are fed to the auto-pilot consisting of the reference optimal controls plus correction terms that are linear combinations of the state deviations from reference values, weighted by a set of pre-calculated gains. In contrast to the neighboring optimal guidance scheme, the reference control and state variables as well as the feedback gains are stored as functions of velocity and path angle in the present approach. Numerical results comparing open loop optimal and approximate feedback solutions are presented. These results demonstrate close agreement between the feedback and optimal trajectories for flight in the vertical plane.

CONTROL AND STABILIZATION OF NONHOLONOMIC DYNAMIC SYSTEMS Ph.D. Thesis
Mahmut Reyhanoglu 1992 109 p
Avail: Univ. Microfilms Order No. DA9303808

A theoretical framework is established for the control of nonholonomic dynamic systems, i.e., dynamic systems with nonintegrable constraints. In particular, we emphasize control properties for nonholonomic systems that have no counterpart in holonomic systems. A model for nonholonomic dynamic systems is first presented in terms of differential-algebraic equations defined on a phase space. A reduction procedure is carried out to obtain reduced order state equations. Feedback is then used to obtain a control system in a normal form. The assumptions guarantee that the resulting normal form equations necessarily contain a nontrivial drift vector field. Conditions for smooth (C infinity) asymptotic stabilization to an m-dimensional equilibrium manifold are presented; we also demonstrate that a single equilibrium solution cannot be asymptotically stabilized using continuous static or dynamic state feedback. However, any equilibrium is shown to be strongly accessible and small time locally controllable. An approach using geometric phases is developed as a basis for the control of Caplygin dynamical systems, i.e., nonholonomic systems with certain symmetry properties which can be expressed by the fact that the constraints are cyclic in certain variables. The theoretical development is applied to physical

examples of systems that we have studied in detail elsewhere; the control of a knife edge moving on a plane surface and the control of a wheel rolling without slipping on a plane surface. The results are also applied to the reorientation of planar multi body systems using joint torque inputs and to the reorientation of a rigid spacecraft using momentum wheel actuators, since in these examples conservation of angular momentum gives rise to nonintegrable motion invariants. Dissert. Abstr.

A system for improving yaw control at low speeds consists of one strake placed on the upper portion of the fuselage facing the retreating rotor blade and another strake placed on the lower portion of the fuselage facing the advancing rotor blade. These strakes spoil the airflow on the helicopter tail boom during hover, low speed flight, and right or left sidewards flight so that less side thrust is required from the tail rotor.

TECHNIQUES FOR DESIGNING ROTORCRAFT CONTROL SYSTEMS Annual Report, 1 Apr. 1992 - 31 Mar. 1993
William S. Levine and Jewel Barlow 5 Apr. 1993 48 p
(Grant NAG2-794)
(NASA-CR-192960; NAS 1.26:192960) Avail: CASI HC A03/MF A01

This report summarizes the work that was done on the project from 1 Apr. 1992 to 31 Mar. 1993. The main goal of this research is to develop a practical tool for rotorcraft control system design based on interactive optimization tools (CONSOL-OPTCAD) and classical rotorcraft design considerations (ADOCS). This approach enables the designer to combine engineering intuition and experience with parametric optimization. The combination should make it possible to produce a better design faster than would be possible using either pure optimization or pure intuition and experience. We emphasize that the goal of this project is not to develop an algorithm. It is to develop a tool. We want to keep the human designer in the design process to take advantage of his or her experience and creativity. The role of the computer is to perform the calculation necessary to improve and to display the performance of the nominal design. Briefly, during the first year we have connected CONSOL-OPTCAD, an existing software package for optimizing parameters with respect to multiple performance criteria, to a simplified nonlinear simulation of the UH-60 rotorcraft. We have also created mathematical approximations to the Mil-specs for rotorcraft handling qualities and input them into CONSOL-OPTCAD. Finally, we have developed the additional software necessary to use CONSOL-OPTCAD for the design of rotorcraft controllers. Author (revised)

DEVELOPMENT AND TESTING OF THE DIGITAL CONTROL SYSTEM FOR THE ARCHYTAS UNMANNED AIR VEHICLE M.S. Thesis
Paul V. Merz Dec. 1992 100 p
(AD-A261656) Avail: CASI HC A05/MF A02

The purpose of this study was to develop the digital sampling and control system for an Unmanned Air Vehicle (UAV) designed to takeoff and land vertically and to transition to forward flight. The system is designed to operate from a personal computer through an umbilical cable tethered to the platform for hover tests. The computer controls the sampling and digital conversion of onboard analog sensor signals and sends control-surface commands for pitch, roll, and yaw motions. The thesis effort includes the following four parts: (1) design of a controllable Pulse-Width-Modulated signal to command the servos which operate the various aerodynamic surfaces; (2) sampling and conversion of the signals to the sensors through the programming of an analog-to-digital card installed in the computer; (3) sensor Power-up and parameter verification of onboard devices; and (4) development of various power networks to allow operation of onboard systems prior to engine start with the ability to be self-sustaining once the engine is running. The system was fully tested during ground runs on a thrust/torque test stand. Integration of the system with the robust controller designed in a concurrent thesis will provide for the stability necessary for the innovative unmanned vehicle. DTIC

HELICOPTER FORCED RESPONSE VIBRATION ANALYSIS METHOD RTVIB20 Final Report, Jan. 1990 - Jun. 1992
Joseph Fries Feb. 1993 33 p
(DA Proj. 1L1-62618-AH-80)
(AD-A261809; ARL-TR-75) Avail: CASI HC A03/MF A01

This report describes a helicopter vibration analysis method. In the method the rotor forcing for a single main rotor is calculated by integrating the forces and moments at the rotor center and then applying them to a rigid helicopter airframe. The vibrations (any place in the airframe) are calculated as the response to the applied hub center forces and moments. The method of analysis allows for dissimilar blades in the main rotor to simulate various types of blade damage and the resulting increase in vibrations transmitted into the airframe. The analysis method is generic and can be used to analyze any single main rotor helicopter. An application is made for the UH-60A helicopter, resulting from the loss of outboard sections of one blade of the rotor, and the resulting vibrations in the cockpit are calculated. DTIC

A transmission system is provided for a transfer device gripping a double wheel, intended to move an aircraft or other wheeled device over a base. The transfer device includes at least two friction rollers and motors to drive them, namely one for each ground wheel of the device to be moved. Compression devices are provided to create the compression to press the friction rollers against the ground wheel. The transmission system includes a power device and transmission devices to feed the operating power to the motors. The intention of the invention is to create a transmission

for a transfer device that creates a steady push irrespective of a poor location of the pushing point, which is the main undercarriage. The system according to the invention includes devices to feed the operating power separately and independently of each other to each of the motors driving the ground wheel. Author (CISTI)

Damaged airbase facilities critical to restoring aircraft operations must be repaired quickly after an attack to provide the needed support. Repair technologies have been developed in earthquake damage research which have potential application to bomb damage repair. This report describes the repair techniques developed for earthquake damage and their potential application to bomb damage repair. Although the damage mechanisms from earthquake loads are quite different from damage mechanisms of blast loads, the damage resulting to structural elements can be quite similar. Typical damages and failure mechanisms are categorized and compared for earthquake and conventional weapon loadings. Typical structures are selected based upon design guidelines. Damages expected to the typical structures from conventional weapon attack are described. Functional damages are defined and methods for accomplishing facility repairs are then recommended depending upon the facility function and the degree of damage. Materials, equipment, and procedures developed for repairing earthquake damage are described along with their potential use in repairing bomb damages. DTIC

DEVELOPMENT AND USE OF HYDROGEN-AIR TORCHES IN AN ALTITUDE FACILITY
Roy A. Lottig and Gary T. Huber (Sverdrup Technology, Inc., Brook Park, OH.) Jun. 1993 15 p Prepared for presentation at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE
(RTOP 505-62-84)
(NASA-TM-106047; E-7633; NAS 1.15:106047; AIAA Paper 93-2176)
Avail: CASI HC A03/MF A01

A hydrogen-air ignition torch concept that had been used successfully in two rocket engine test facilities to consume excess hydrogen in their exhausters at atmospheric conditions was experimentally evaluated and developed in an altitude test facility at NASA Lewis Research Center. The idea was to use several of these torches in conjunction with hydrogen detectors and dilution air to prevent excess accumulation of unburned hydrogen or mixtures of hydrogen and air exceeding the sea-level lower flammability limit in the altitude facility exhaust system during hydrogen-fueled propulsion system tests. The torches were evaluated for a range of fuel-to-air ratios from 0.09 to 0.39 and for a range of exit diameters from 19/64 to 49/64 in. From the results of these tests a torch geometry and a fuel-to-air ratio were selected that produced a reasonably sized torch exhaust flame for consumption of unburned hydrogen at altitude pressures from sea level to 4 psia. The Advanced Photon Source (APS), which is currently under construction as a national user facility at Argonne National Laboratory is a third-generation synchrotron x-ray source, one of only three in the world. It is expected to produce x-rays that are 10,000 times brighter than any currently produced elsewhere for use in research in a wide range of scientific areas. Users from industry, national laboratories, universities, and business will be able to come to the APS to conduct research either as members of Collaborative Access Teams (CAT's) or as Independent Investigators. Principal users will be members of CAT's, which will be building and operating all of the beamlines present in the first phase of APS beamline development. The first set of CAT's has been selected through a competitive proposal process involving peer scientific review, thorough technical evaluation, and significant management oversight by the APS. This document is a compilation of posters presented at the Fifth Users Meeting for the Advanced Photon Source, held at Argonne National Laboratory on October 14-15, 1992. All CAT's whose scientific cases were approved by the APS Proposal Evaluation Board are included. In addition, this document contains a poster from the Center for Synchrotron Radiation and Research and Instrumentation at the Illinois Institute of Technology. DOE

The analysis and design of robust controllers for multivariable discrete-time feedback systems in the frequency domain are studied. The robustness stability conditions for discrete-time systems with additive alteration, and with multiplicative alteration are developed. The robust LQG/LTR method has been extended from the continuous-time system to the discrete-time system. It has been proven that the LQG/LTR method is also valid for the LQG control of the discrete-time system with the filtering observer. As an application of the LQG/LTR technique for discrete-time systems, the design of reduced order optimal digital LQG controllers for the orbiting flexible shallow spherical shell system is considered. The comparison between the digital optimal LQG controller with the filtering observer and with the predicting observer for the orbiting flexible shallow spherical shell has been made. DTIC

(Contract NAS2-13296)
(NASA-CR-193048; NAS 1.26:193048) Avail: CASI HC A07/MF A02

A complete Personal Analysis Assistant (PAA) for Space Station Freedom (SSF) assembly sequence planning consists of three software components: the system infrastructure, intra-flight value added, and inter-flight value added. The system infrastructure is the substrate on which software elements providing inter-flight and intra-flight value-added functionality are built. It provides the capability for building representations of assembly sequence plans and specification of constraints and analysis options. Intra-flight value-added provides functionality that will, given the manifest for each flight, define cargo elements, place them in the National Space Transportation System (NSTS) cargo bay, compute performance measure values, and identify violated constraints. Inter-flight value-added provides functionality that will, given major milestone dates and capability requirements, determine the number and dates of required flights and develop a manifest for each flight. The current project is Phase 1 of a projected two phase program and delivers the system infrastructure. Intra- and inter-flight value-added were to be developed in Phase 2, which has not been funded. Based on experience derived from hundreds of projects conducted over the past seven years, ISX developed an Intelligent Systems Engineering (ISE) methodology that combines the methods of systems engineering and knowledge engineering to meet the special systems development requirements posed by intelligent systems, systems that blend artificial intelligence and other advanced technologies with more conventional computing technologies. The ISE methodology defines a phased program process that begins with an application assessment designed to provide a preliminary determination of the relative technical risks and payoffs associated with a potential application, and then moves through requirements analysis, system design, and development. SPACE TRANSFER CONCEPTS AND ANALYSES FOR EXPLORATION MISSIONS. TECHNICAL DIRECTIVE 12: BEAMED POWER SYSTEMS STUDY Final Report
D. Eder Dec. 1992 71 p
(Contract NAS8-37857)
(NASA-CR-192532; NAS 1.26:192532; D615-10050) Avail: CASI HC A04/MF A01

Parametric models were constructed for Earth-based laser powered electric orbit transfer from low Earth orbit to geosynchronous orbit. These models were used to carry out performance, cost/benefit, and sensitivity analyses of laser-powered transfer systems including end-to-end life cycle cost analyses for complete systems. Comparisons with conventional orbit transfer systems were made indicating large potential cost savings for laser-powered transfer. Approximate optimization was done to determine best parameter values for the systems. Orbit transfer flights simulations were conducted to explore effects of parameters not practical to model with a spreadsheet. The simulations considered view factors that determine when power can be transferred from ground stations to an orbit transfer vehicle and conducted sensitivity analyses for numbers of ground stations, Isp including dual-Isp transfers, and plane change profiles. Optimal steering laws were used for simultaneous altitude and plane change. Viewing geometry and low-thrust orbit raising were simultaneously simulated. A very preliminary investigation of relay mirrors was made. Author (revised)

MOMENTUM ACCUMULATION DUE TO SOLAR RADIATION TORQUE, AND REACTION WHEEL SIZING, WITH CONFIGURATION OPTIMIZATION **c18**

Hari B. Hablani *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 3-22 (For primary document see N93-24694 09-13)

This paper has a two-fold objective: determination of yearly momentum accumulation due to solar radiation pressure, and optimum reaction wheel sizing. The first objective is confronted while determining propellant consumption by the attitude control system over a spacecraft's lifetime. This, however, cannot be obtained from the daily momentum accumulation and treating that constant throughout the year, because the orientation of the solar arrays relative to the spacecraft changes over a wide range in a year, particularly if the spacecraft has two arrays, one normal and the other off-normal to different extent at different times to the sun rays. The paper first develops commands for the arrays for tracking the sun, the arrays articulated to earth-pointing spacecraft with two rotational degrees of freedom, and spacecraft in an arbitrary circular orbit. After developing expressions for solar radiation torque due to one or both arrays, arranged symmetrically or asymmetrically relative to the spacecraft bus, momentum accumulation over an orbit and then over a year are determined. The remainder of the paper is concerned with designing reaction wheel configurations. Four-, six-, and three-wheel configurations are considered, and for given torque and momentum requirements, their cant angles with the roll/yaw plane are optimized for minimum power consumption. Finally, their momentum and torque capacities are determined for one-wheel failure scenario, and six configurations are compared and contrasted. Author

The attitude motion of a tumbling, rigid, axisymmetric spacecraft is considered. A methodology for detumbling the spacecraft through energy dissipation is presented. The differential equations governing this motion are stiff, and therefore an approximate solution, based on the variation of constants method, is developed and utilized in the analysis of the detumbling strategy. Stability of the detumbling process is also addressed. Author

The Arthur Holly Compton Gamma Ray Observatory (GRO) was launched by the shuttle Atlantis in April 1991. This paper presents the results of the attitude sensor calibration that was performed during the early mission. The GSFC Flight Dynamics Facility (FDF) performed an alignment calibration of the two fixed-head star trackers (FHST's) and two fine Sun sensors (FSS's) on board Compton GRO. The results show a 27-arcsecond shift between the bore sights of the FHST's with respect to prelaunch measurements. The alignments of the two FSS's shifted by 0.20 and 0.05 degree. During the same time period, the Compton GRO science teams performed an alignment calibration of the science instruments with respect to the attitude reported by the on board computer (OBC). In order to preserve these science alignments, FDF adjusted the overall alignments of the FHST's and FSS's, obtained by the FDF calibration, such that when up linked to the OBC, the shift in the OBC-determined attitude is minimized. FDF also calibrated the inertial reference unit (IRU), which consists of three dual-axis gyroscopes. The observed gyro bias matched the bias that was solved for by the OBC. This bias drifted during the first 6 days after release. The results of the FDF calibration of scale factor and alignment shifts showed changes that were of the same order as their uncertainties. Algorithms for on-board attitude determination and control of the Solar, Anomalous, and Magnetospheric Particle Explorer (SAMPEX) have been expanded to include a constant gain Kalman filter for the spacecraft angular momentum, pulse width modulation for the reaction wheel command, an algorithm to avoid pointing the Heavy Ion Large Telescope (HILT) instrument boresight along the spacecraft velocity vector, and the addition of digital sun sensor (DSS) failure detection logic. These improved algorithms were tested in a closed-loop environment for three orbit geometries, one with the sun perpendicular to the orbit plane, and two with the sun near the orbit plane - at Autumnal Equinox and at Winter Solstice. The closed-loop simulator was enhanced and used as a truth model for the control systems' performance evaluation and sensor/actuator contingency analysis. The simulations were performed on a VAX 8830 using a prototype version of the on-board software. Author

Algorithms that reject transient signals due to proton effects on charge coupled device (CCD) sensors have been implemented in the HDOS ASTRA-I Star Trackers to be flown on the TOPEX mission scheduled for launch in July 1992. A unique technique for simulating a proton-rich environment to test trackers is described, as well as the test results obtained. Solar flares or an orbit that passes through the South Atlantic Anomaly can subject the vehicle to very high proton flux levels. There are three ways in which spurious proton generated signals can impact tracker performance: the many false signals can prevent or extend the time to acquire a star; a proton-generated signal can compromise the accuracy of the star's reported magnitude and position; and the tracked star can be lost, requiring reacquisition. Tests simulating a proton-rich environment were performed on two ASTRA-1 Star Trackers utilizing these new algorithms. There were no false acquisitions, no lost stars, and a significant reduction in reported position errors due to these improvements. Author

RESOLUTION OF THE COBE EARTH SENSOR ANOMALY **c19**

J. Sedler *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 83-99 (For primary document see N93-24694 09-13)

Copyright Avail: CASI HC A03/MF A04

Since its launch on November 18, 1989, the Earth sensors on the Cosmic Background Explorer (COBE) have shown much greater noise than expected. The problem was traced to an error in Earth horizon acquisition-of-signal (AOS) times. Due to this error, the AOS timing correction was ignored, causing Earth sensor split-to-index (SI) angles to be incorrectly time-tagged to minor frame synchronization times. Resulting Earth sensor residuals, based on gyro-propagated fine attitude solutions, were as large as plus or minus 0.45 deg (much greater than plus or minus 0.10 deg from scanner specifications (Reference 1)). Also, discontinuities in single-frame coarse attitude pitch and roll angles (as large as 0.80 and

0.30 deg, respectively) were noted several times during each orbit. However, over the course of the mission, each Earth sensor was observed to independently and unexpectedly reset and then reactivate into a new configuration. Although the telemetered AOS timing corrections are still in error, a procedure has been developed to approximate and apply these corrections. This paper describes the approach, analysis, and results of approximating and applying AOS timing adjustments to correct Earth scanner data. Furthermore, due to the continuing degradation of COBE's gyroscopes, gyro-propagated fine attitude solutions may soon become unavailable, requiring an alternative method for attitude determination. By correcting Earth scanner AOS telemetry, as described in this paper, more accurate single-frame attitude solutions are obtained. All aforementioned pitch and roll discontinuities are removed. When proper AOS corrections are applied, the standard deviation of pitch residuals between coarse attitude and gyro-propagated fine attitude solutions decrease by a factor of 3. Also, the overall standard deviation of SI residuals from fine attitude solutions decrease by a factor of 4 (meeting sensor specifications) when AOS corrections are applied. Author

TDRSS ORBIT DETERMINATION USING SHORT BASELINE DIFFERENCED CARRIER PHASE
S. Nandi, C. D. Edwards, and S. C. Wu *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 103-115 (For primary document see N93-24694 09-13)
Copyright Avail: CASI HC A03/MF A04

This paper discusses a covariance study on the feasibility of using station-differenced carrier phase on short baselines to track the TDRSS satellites. Orbit accuracies for the TDRSS using station-differenced carrier phase data and range data collected from White Sands, NM are given for various configurations of ground stations and range data precision. A one-sigma-position position accuracy of 25 meters can be achieved using two orthogonal baselines of 100 km for the station-differenced phase data and range data with 1 m accuracy. Relevant configuration parameters for the tracking system and important sources of error are examined. The ability of these data to redetermine the position after a station keeping maneuver is addressed. The BRTS system, which is currently used for TDRSS orbit determination, is briefly described and its errors are given for comparison. Author

In this paper, we evaluate two fundamentally different approaches to TDRS orbit determination utilizing Global Positioning System (GPS) technology and GPS-related techniques. In the first, a GPS flight receiver is deployed on the TDRSS spacecraft. The TDRS ephemerides are determined using direct ranging to the GPS spacecraft, and no ground network is required. In the second approach, the TDRSS spacecraft broadcast a suitable beacon signal, permitting the simultaneous tracking of GPS and TDRSS satellites from a small ground network. Both strategies can be designed to meet future operational requirements for TDRS-2 orbit determination. Author

The Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD) commissioned Applied Technology Associates, Incorporated, to develop the Real-Time Orbit Determination/Enhanced (RTOD/E) system on a Disk Operating System (DOS)-based personal computer (PC) as a prototype system for sequential orbit determination of spacecraft. This paper presents the results of a study to compare the orbit determination accuracy for a Tracking and Data Relay Satellite System (TDRSS) user spacecraft, Landsat-4, obtained using RTOD/E, operating on a PC, with the accuracy of an established batch least-squares system, the Goddard Trajectory Determination System (GTDS), and operating on a mainframe computer. The results of Landsat-4 orbit determination will provide useful experience for the Earth Observing System (EOS) series of satellites. The Landsat-4 ephemerides were estimated for the January 17-23, 1991, timeframe, during which intensive TDRSS tracking data for Landsat-4 were available. Independent assessments were made of the consistencies (overlap comparisons for the batch case and covariances and the first measurement residuals for the sequential case) of solutions produced by the batch and sequential methods. The forward-filtered RTOD/E orbit solutions were compared with the definitive GTDS orbit solutions for Landsat-4; the solution differences were less than 40 meters after the filter had reached steady state. The Ocean Topography Experiment (TOPEX/Poseidon) mission is designed to determine the topography of the Earth's sea surface over a 3-year period, beginning shortly after launch in July 1992. TOPEX/Poseidon is a joint venture between the United States National Aeronautics and Space Administration (NASA) and the French Centre Nationale d'Etudes Spatiales. The Jet Propulsion Laboratory is NASA's TOPEX/Poseidon project center. The Tracking and Data Relay Satellite System (TDRSS) will nominally be used to support the day-to-day orbit determination aspects of the mission. Due to its extensive experience with TDRSS tracking data, the NASA Goddard Space Flight Center (GSFC) Flight Dynamics Facility (FDF) will receive and process TDRSS observational data. To fulfill the scientific goals of the mission, it is necessary to achieve and maintain a very precise orbit. The most stringent accuracy requirements are associated with planning and evaluating orbit maneuvers, which will place the spacecraft in its mission orbit and maintain the required ground track. To determine if the FDF can meet the TOPEX/Poseidon maneuver accuracy requirements, covariance analysis was undertaken with the Orbit Determination Error Analysis System (ODEAS). The covariance analysis addressed many aspects of TOPEX/Poseidon orbit determination, including arc length, force models, and other processing options. The most recent analysis has focused on determining the size of the geopotential field necessary to meet the maneuver support requirements. Analysis was undertaken with the full 50 x 50 Goddard Earth Model (GEM) T3 field as well as smaller representations of this model. Author

Future NASA Earth Observing System (EOS) Spacecraft will make measurements of the earth's clouds, oceans, atmosphere, land and radiation balance. These EOS Spacecraft will be part of the NASA Mission to Planet Earth. This paper specifically addresses the EOS AM Spacecraft, referred to as 'AM' because it has a sun-synchronous orbit with a 10:30 AM descending node. This paper describes the EOS AM Spacecraft mission

orbit requirements, orbit determination, orbit control, and navigation system impact on earth based pointing. The EOS AM Spacecraft will be the first spacecraft to use the TDRSS Onboard Navigation System (TONS) as the primary means of navigation. TONS flight software will process one-way forward Doppler measurements taken during scheduled TDRSS contacts. An extended Kalman filter will estimate spacecraft position, velocity, drag coefficient correction, and ultrastable master oscillator frequency bias and drift. The TONS baseline algorithms, software, and hardware implementation are described in this paper. TONS integration into the EOS AM Spacecraft Guidance, Navigation, and Control (GN&C) System; TONS assisted onboard time maintenance; and the TONS Ground Support System (TGSS) are also addressed. ANALYSIS OF THE EFFECTS OF MEAN LOCAL NODE-CROSSING TIME ON THE EVOLUTION OF SUN-SYNCHRONOUS ORBITS

P. Jordan (Computer Sciences Corp., Lanham, MD.), V. Blaes (Computer Sciences Corp., Lanham, MD.), L. Roszman (Computer Sciences Corp., Lanham, MD.), and J. Cooley *In its* Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 177-190 (For primary document see N93-24694 09-13)

(Contract NAS5-31500)

Copyright Avail: CASI HC A03/MF A04

An investigation of the effect of mean local node-crossing time on the evolution of Sun-synchronous orbits was undertaken during Phase-A orbit analysis for the National Oceanic and Atmospheric Administration (NOAA) O,P,Q environmental spacecraft. That analysis added to the growing body of evidence that individual Sun-synchronous missions, at differing node-crossing times, experience nodal drift rates that can differ in both magnitude and direction. A Sun-synchronous orbit is obtained by means of a nodal drift rate approximating the 0.9856-degree-per-day apparent precession of the position of the mean Sun. This drift rate is achieved through the interaction of the orbital semimajor axis and inclination in Earth's geopotential field. Influencing perturbations include atmospheric drag and, most important, the effects of solar gravitation on inclination. The present analysis examines a series of Sun-synchronous orbits with mean local node-crossing times at 1-hour intervals from 6 a.m. to 6 p.m. It considers the fixed geometry of each orbital plane with respect to both the Sun and the diurnal atmospheric bulge, then analyzes the influence of these features upon the evolution of the semimajor axix and inclination and thus upon the rate of the nodal drift in the course of 1 year. The results of an analysis of an algorithm that will provide autonomous onboard orbit control using orbits determined with Global Positioning System (GPS) data. The algorithm uses the GPS data to (1) compute the ground track error relative to a fixed longitude grid, and (2) determine the altitude adjustment required to correct the longitude error. A program was written on a personal computer (PC) to test the concept for numerous altitudes and values of solar flux using a simplified orbit model including only the J sub 2 zonal harmonic and simple orbit decay computations. The algorithm was then implemented in a precision orbit propagation program having a full range of perturbations. The analysis showed that, even with all perturbations (including actual time histories of solar flux variation), the algorithm could effectively control the spacecraft ground track and yield more than 99 percent Earth coverage in the time required to complete one coverage cycle on the fixed grid (220 to 230 days depending on altitude and overlap allowance). We present results for two real-time filters prototyped for the Compton Gamma Ray Observatory (GRO), the Extreme Ultraviolet Explorer (EUVE), the Cosmic Background Explorer (COBE), and the next generation of Geostationary Operational Environmental Satellites (GOES). Both real and simulated data were used to solve for attitude and gyro biases. These filters promise advantages over single-frame and batch methods for missions like GOES, where startup and transfer-orbit operations require quick knowledge of attitude and gyro biases. Author

For many practical spacecraft applications, algorithms for determining spacecraft attitude must combine inputs from diverse sensors and provide redundancy in the event of sensor failure. A Kalman filter is suitable for this task, however, it may impose a computational burden which may be avoided by sub optimal methods. A suboptimal estimator is presented which was implemented successfully on the Delta Star spacecraft which performed a 9 month SDI flight experiment in 1989. This design sought to minimize algorithm complexity to accommodate the limitations of an 8K guidance computer. The algorithm used is interpreted in the framework of Kalman filtering and a derivation is given for the computation. Author

Previous papers have described the modification of the Earth Radiation Budget Satellite (ERBS) Attitude Determination System (ADS) to overcome the impact of on board gyro degradation and failure on attitude ground support of the mission. Two approaches were taken: implementing a Kalman filter in place of the batch-least-squares attitude estimator to account for the propagation error produced by high-noise gyro data, and modeling the ERBS attitude dynamics to restore rate information in the case of gyro failure. Both of these methods had shortcomings. In practice, the filter attitude diverged without complete sensor observability, and accurate dynamics modeling required knowledge of disturbance torque parameters that had to be determined manually. These difficulties have been overcome by improved tuning of the filter and by incorporating dynamics parameter estimation into the ERBS ADS. Author

This work treats the problem of weighted least squares fitting of a 3D Euclidean-coordinate transformation matrix to a set of unit vectors measured in the reference and transformed coordinates. A closed-form analytic solution to the problem is re-derived. The fact that the solution is the closest orthogonal matrix to some matrix defined on the measured vectors and their weights is clearly demonstrated. Several known algorithms for computing the analytic closed form solution are considered. An algorithm is discussed which is based on the polar decomposition of matrices into the closest unitary matrix to the decomposed matrix and a Hermitian matrix. A somewhat

longer improved algorithm is suggested too. A comparison of several algorithms is carried out using simulated data as well as real data from the Upper Atmosphere Research Satellite. The comparison is based on accuracy and time consumption. It is concluded that the algorithms based on polar decomposition yield a simple although somewhat less accurate solution. The precision of the latter algorithms increase with the number of the measured vectors and with the accuracy of their measurement.

Many results in attitude analysis are still meaningful when the attitude is restricted to rotations about a single axis. Such a picture corresponds to attitude analysis in the Euclidean plane. The present report formalizes the representation of attitude in the plane and applies it to some well-known problems. In particular, we study the connection of the 'additive' and 'multiplicative' formulations of the differential corrector for the quaternion in its two-dimensional setting.

Vector observations are a common class of attitude data provided by a wide variety of attitude sensors. Attitude determination from vector observations is a well-understood process and numerous algorithms such as the TRIAD algorithm exist. These algorithms require measurement of the line of site (LOS) vector to reference objects and knowledge of the LOS directions in some predetermined reference frame. Once attitude is determined, it is a simple matter to synthesize vehicle rate using some form of lead-lag filter, and then, use it for vehicle stabilization. Many situations arise, however, in which rate knowledge is required but knowledge of the nominal LOS directions are not available. This paper presents two methods for determining spacecraft angular rates from vector observations without a priori knowledge of the vector directions. The first approach uses an extended Kalman filter with a spacecraft dynamic model and a kinematic model representing the motion of the observed LOS vectors. The second approach uses a 'differential' TRIAD algorithm to compute the incremental direction cosine matrix, from which vehicle rate is then derived.

The Multimission Three-Axis Stabilized Spacecraft (MTASS) Flight Dynamics Support System (FDSS) has been developed in an effort to minimize the costs of ground support systems. Unlike single-purpose ground support systems, which attempt to reduce costs by reusing software specifically developed for previous missions, the multimission support system is an intermediate step in the progression to a fully generalized mission support system in which numerous missions may be served by one general system. The benefits of multimission attitude ground support systems extend not only to the software design and coding process, but to the entire system environment, from specification through testing, simulation, operations, and maintenance. This paper reports the application of an MTASS FDSS to multiple scientific satellite missions. The satellites are the Upper Atmosphere Research Satellite (UARS), the Extreme Ultraviolet Explorer (EUVE), and the Solar Anomalous Magnetospheric Particle Explorer (SAMPEX). Both UARS and EUVE use the multimission modular spacecraft (MMS) concept. SAMPEX is part of the Small Explorer (SMEX) series and uses a much simpler set of attitude sensors. This paper centers on algorithm and design concepts for a multimission system and discusses flight experience from UARS.

This experiment was designed to find a function of payload weight for altitude. The same rocket was launched a repeated number of times with the same engine and varying amounts of weight. After performing experimentation, it was calculated that the altitude in meters could be predicted with the equation A = (2.8(W exp 2)) - (70.6W + 310.3), with weight expressed in the unit ounces.

This paper presents numerical techniques for constructing nonlinear predictive models to forecast solar flux directly from its time series. This approach makes it possible to extract dynamical in variants of our system without reference to any underlying solar physics. We consider the dynamical evolution of solar activity in a reconstructed phase space that captures the attractor (strange), give a procedure for constructing a predictor of future solar activity, and discuss extraction of dynamical invariants such as Lyapunov exponents and attractor dimension.

(Contract NAS5-31500)
Copyright Avail: CASI HC A03/MF A04

This study investigates the reentry of the LifeSat vehicles into the WSMR. The LifeSat mission consists of two reusable reentry satellites, each carrying a removable payload module, which scientists will use to study long-term effects of microgravity, Van Allen belt radiation, and galactic cosmic rays on living organisms. A series of missions is planned for both low-Earth circular orbits and highly elliptic orbits. To recover the payload module with the specimens intact, a soft parachute landing and recovery at the WSMR is planned. This analysis examines operational issues surrounding the reentry scenario to assess the feasibility of the reentry.

TSIEN'S METHOD FOR GENERATING NON-KEPLERIAN TRAJECTORIES. PART 2: THE QUESTION OF THRUST TO ORBIT A SPHERE AND THE RESTRICTED THREE-BODY PROBLEM
P. A. Murad *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 351-368
(For primary document see N93-24694 09-13)

Tsien's method is extended to treat the orbital motion of a body undergoing accelerations and decelerations. A generalized solution is discussed for the generalized case where a body undergoes azimuthal and radial thrust and the problem is further simplified for azimuthal thrust alone. Judicious selection of thrust could generate either an elliptic or hyperbolic

trajectory. This is unexpected especially when the body has only enough energy for a lower state trajectory. The methodology is extended treating the problem of vehicle thrust for orbiting a sphere and vehicle thrust within the classical restricted three-body problem. Results for the latter situation can produce hyperbolic trajectories through eigen value decomposition. Since eigen values for no-thrust can be imaginary, thrust can generate real eigen values to describe hyperbolic trajectories. Keplerian dynamics appears to represent but a small subset of a much larger non-Keplerian domain especially when thrust effects are considered. The need for high thrust long duration space-based propulsion systems for changing a trajectory's canonical form is clearly demonstrated. Author

PRACTICAL ASPECTS OF TRANSFER FROM GTO TO LUNAR ORBIT
Chauncey Uphoff *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 369-380 Sponsored in part by LunCorp., Inc. (For primary document see N93-24694 09-13)
Copyright Avail: CASI HC A03/MF A04

This paper is a presentation of some practical aspects of orbital transfer from Geosynchronous Transfer Orbit (GTO) to close, near-circular orbits of the Moon. The intent is to identify the important parameters affecting the problem and to bound (approximately) the range of required delta V for a spacecraft that has been placed in GTO. The basic geometric relationships are described and the dynamics are simulated by use of the Zero-Sphere-of Influence Patched Conic method. It is found that the inclination of the transfer orbit to the Earth-Moon plane is relatively unimportant while the position of the line of apsides with respect to the Moon's orbit is the main geometric parameter of interest. It is shown that this parameter can be controlled by selecting the time of day for launch and that two launch windows of approximately 45 minutes duration are available each day of the year if use is made of the recommended phasing orbit transfer. The phasing orbit transfer not only provides twice-daily launch windows, but also provides a mechanism for efficacious correction of GTO injection errors. Delta V penalties for out-of-plane transfer and for late launch are evaluated and the method is recommended for use as an affordable means of achieving lunar orbit. Author

AN APPROACH FOR FINDING LONG PERIOD ELLIPTICAL ORBITS FOR PRECURSOR SEI MISSIONS
Michael F. Fraietta and Victor R. Bond *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 381-394 (For primary document see N93-24694 09-13)

Precursors for Solar System Exploration Initiative (SEI) missions may require long period elliptical orbits about a planet. These orbits will typically have periods on the order of tens to hundreds of days. Some potential uses for these orbits may include the following: studying the effects of galactic cosmic radiation, parking orbits for engineering and operational test of systems, and ferrying orbits between libration points and low altitude orbits. This report presents an approach that can be used to find these orbits. The approach consists of three major steps. First, it uses a restricted three-body targeting algorithm to determine the initial conditions which satisfy certain desired final conditions in a system of two massive primaries. Then the initial conditions are transformed to an inertial coordinate system for use by a special perturbation method. Finally, using the special perturbation method, other perturbations (e.g., sun third body and solar radiation pressure) can be easily incorporated to determine their effects on the nominal trajectory. An algorithm potentially suitable for on-board guidance will also be discussed. This algorithm uses an analytic method relying on Chebyshev polynomials to compute the desired position and velocity of the satellite as a function of time. Together with navigation updates, this algorithm can be implemented to predict the size and timing for AV corrections. Author

Spacecraft in orbit near libration point L1 in the Sun-Earth system are excellent platforms for research concerning solar effects on the terrestrial environment. One spacecraft mission launched in 1978 used an L1 orbit for nearly 4 years, and future L1 orbital missions are also being planned. Orbit determination and station-keeping are, however, required for these orbits. In particular, orbit determination error analysis may be used to compute the state uncertainty after a predetermined tracking period; the predicted state uncertainty levels then will impact the control costs computed in station-keeping simulations. Error sources, such as solar radiation pressure and planetary mass uncertainties, are also incorporated. For future missions, there may be some flexibility in the type and size of the spacecraft's nominal trajectory, but different orbits may produce varying error analysis and station-keeping results. The nominal path, for instance, can be (nearly) periodic or distinctly quasi-periodic. A periodic 'halo' orbit may be constructed to be significantly larger than a quasi-periodic 'Lissajous' path; both may meet mission requirements, but perhaps the required control costs for these orbits are probably different. Also for this spacecraft tracking and control simulation problem, experimental design methods can be used to determine the most significant uncertainties. That is, these methods can determine the error sources in the tracking and control problem that most impact the control cost (output); it also produces an equation that gives the approximate functional relationship between the error inputs and the output. ANALYSIS OF THE COMMAND AND CONTROL SEGMENT (CCS) ATTITUDE ESTIMATION ALGORITHM **c61**
Catherine Stockwell *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 413-421 Prepared for Consolidated Space Test Center, Onizuka AFB, CA (For primary document see N93-24694 09-13)
Copyright Avail: CASI HC A02/MF A04

This paper categorizes the qualitative behavior of the Command and Control Segment (CCS) differential correction algorithm as applied to attitude estimation using simultaneous spin axis sun angle and Earth cord length measurements. The categories of interest are the domains of convergence, divergence, and their boundaries. Three series of plots are discussed that show the dependence of the estimation algorithm on the vehicle radius, the sun/Earth angle, and the spacecraft attitude. Common qualitative dynamics to all three series are tabulated and discussed. Out-of-limits conditions for the estimation algorithm are identified and discussed. Author

This paper summarizes the on-orbit performance to date of the three Hubble Space Telescope Fine Guidance Sensors (FGS's) in Fine Lock mode, with respect to acquisition success rate, ability to maintain lock, and star brightness range. The process of optimizing Fine Lock performance, including the reasoning underlying the adjustment of uplink parameters, and the effects of optimization are described. The Fine Lock optimization process has combined theoretical and experimental approaches. Computer models of the FGS have improved understanding of the effects of uplink parameters and fine error averaging on the ability of the FGS to acquire stars and maintain lock. Empirical data have determined the variation of the interferometric error characteristics (so-called 's-curves') between FGS's and over each FGS field of view, identified binary stars, and quantified the systematic error in Coarse Track (the mode preceding Fine Lock). On the basis of these empirical data, the values of the uplink parameters can be selected more precisely. Since launch, optimization efforts have improved FGS Fine Lock performance, particularly acquisition, which now enjoys a nearly 100 percent success rate. More recent work has been directed

towards improving FGS tolerance of two conditions that exceed its original design requirements. First, large amplitude spacecraft jitter is induced by solar panel vibrations following day/night transitions. This jitter is generally much greater than the FGS's were designed to track, and while the tracking ability of the FGS's has been shown to exceed design requirements, losses of Fine Lock after day/night transitions are frequent. Computer simulations have demonstrated a potential improvement in Fine Lock tracking of vehicle jitter near terminator crossings. Second, telescope spherical aberration degrades the interferometric error signal in Fine Lock, but use of the FGS two-thirds aperture stop restores the transfer function with a corresponding loss of throughput. This loss requires the minimum brightness of acquired stars to be about one magnitude brighter than originally planned. Author

THE HUBBLE SPACE TELESCOPE FINE GUIDANCE SYSTEM OPERATING IN THE COARSE TRACK POINTING CONTROL MODE **c89**

Richard Whittlesey *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 439-452 (For primary document see N93-24694 09-13)
(Contract NAS5-38494)
Copyright Avail: CASI HC A03/MF A04

The Hubble Space Telescope (HST) Fine Guidance System has set new standards in pointing control capability for earth orbiting spacecraft. Two precision pointing control modes are implemented in the Fine Guidance System; one being a Coarse Track Mode which employs a pseudo-quadrature detector approach and the second being a Fine Mode which uses a two axis interferometer implementation. The Coarse Track Mode was designed to maintain FGS pointing error to within 20 milli-arc seconds (rms) when guiding on a 14.5 Mv star. The Fine Mode was designed to maintain FGS pointing error to less than 3 milli-arc seconds (rms). This paper addresses the HST FGS operating in the Coarse Track Mode. An overview of the implementation, the operation, and both the predicted and observed on orbit performance is presented. The discussion includes a review of the Fine Guidance System hardware which uses two beam steering Star Selector servos, four photon counting photomultiplier tube detectors, as well as a 24 bit microprocessor, which executes the control system firmware. Unanticipated spacecraft operational characteristics are discussed as they impact pointing performance. These include the influence of spherically aberrated star images as well as the mechanical shocks induced in the spacecraft during and following orbital day/night terminator crossings. Computer modeling of the Coarse Track Mode verifies the observed on orbit performance trends in the presence of these optical and mechanical disturbances. It is concluded that the coarse track pointing control function is performing as designed and is providing a robust pointing control capability for the Hubble Space Telescope. Author

SCATHA MISSION TERMINATION REPORT **c18**

Kjell Stakkestad and Richard Fennessey *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 453-469 Prepared for Consolidated Space Test Center, Onizuka AFB, CA (For primary document see N93-24694 09-13)
Copyright Avail: CASI HC A03/MF A04

The SCATHA (Spacecraft Charging at High Altitudes) satellite was operated from the Consolidated Space Test Center in Sunnyvale, California from February 1979 to May 1991. It was a spin stabilized vehicle in a highly eccentric orbit that collected data on spacecraft charging. The purpose of such data gathering was to predict and/or model the effects of the Earth's magnetic field on synchronous and near synchronous satellites. During the majority of its lifetime, attitude precession maneuvers were done every 10-15 days to maintain solar panel orientation. Maneuver planning was difficult due to the structural characteristics of SCATHA. It is cylindrically shaped and has seven booms ranging in length from 2 to 50 meters. These precession maneuvers induced predictable nutation that damped out after a few days. Eventually fuel began running low due to these frequent maneuvers. Experiments that had required the spin axis be in the orbit plane had already been turned off or had collected all their data. To increase the vehicle lifetime, the spin axis was moved to ecliptic normal. While this stopped the need for frequent attitude maneuvering (only two per year required now), this movement of the spin axis caused nutation that would not damp out for the remainder of the mission. This phase of the mission, with the ecliptic normal orientation, lasted for approximately three years. Although nutation never damped, data gathering was uninterrupted. In late 1990, when SCATHA's transmitter became seriously degraded, the Air Force decided to turn SCATHA off. This would only be done after the satellite was made 'safe'. The most difficult part of making the vehicle safe was quickly purging the fuel. Several plans were considered. The selected plan was to perform a series of 20 degree attitude precession maneuvers (3 days apart to allow for the worst nutation to damp) until the fuel was depleted. Although this sounded simple, the actual execution proved difficult. This was due to a nearly complete lack of available telemetry data, large undamped motion of the long booms, inadequacies in attitude determination software, and an error in the fuel level calculation software. This paper discusses the various proposed termination plans and execution of the selected one. Attitude determination methodologies, nutation from maneuvers, and effects of the flexible booms on the termination mission are presented and analyzed from a satellite analyst point of view. Author

The Low-power Atmospheric Compensation Experiment (LACE) satellite, launched in February 1990 by the Naval Research Laboratory, uses a magnetic damper on a gravity gradient boom and a momentum wheel with its axis perpendicular to the plane of the orbit to stabilize and maintain its attitude. Satellite attitude is determined using three types of sensors: a conical Earth scanner, a set of sun sensors, and a magnetometer. The Ultraviolet Plume Instrument (UVPI), on board LACE, consists of two intensified CCD cameras and a gimbal led pointing mirror. The primary purpose of the UVPI is to image rocket plumes from space in the ultraviolet and visible wavelengths. Secondary objectives include imaging stars, atmospheric phenomena, and ground targets. The problem facing the UVPI experimenters is that the sensitivity of the LACF satellite attitude sensors is not always adequate to correctly point the UVPI cameras. Our solution is to point the UVPI cameras at known targets and use the information thus gained to improve attitude measurements. This paper describes the three methods developed to determine improved attitude values using the UVPI for both real-time operations and post observation analysis. Author

Copyright Avail: CASI HC A03/MF A04

The Low-power Atmospheric Compensation Experiment (LACE) satellite was launched in February 1990 by the Naval Research Laboratory. The spacecraft's pitch and roll are maintained with a gravity gradient boom and a magnetic damper. There are two other booms with much smaller tip masses, one in the velocity direction (lead boom) of variable length and the other in the opposite direction (balance boom) also of variable length. In addition, the system uses a momentum wheel with its axis perpendicular to the plane of the orbit to control yaw and keep these booms in the orbital plane. The primary LACE experiment requires that the lead boom be moved to lengths varying from 4.6 m to 45.7 m. This and other onboard experiments require that the spacecraft attitude remain within tight constraints while operating. The problem confronting the satellite operators was to move the lead boom without inducing a net spacecraft attitude disturbance. A description of a method used to change the length of the lead boom while minimizing the disturbance to the attitude of the spacecraft is given. Deadbeating to dampen pitch oscillations has also been accomplished by maneuvering either the lead or balance boom and is discussed. Author

MINIATURE OPTICAL WIDE-ANGLE-LENS STARTRACKER (MINI-OWLS) **c19**
Rick Miller, Joe E. Coulter (Northrop Corp., Hawthorne, CA.), and Seymour Levine (Northrop Corp., Hawthorne, CA.) *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium, 1992 Feb. 1993 p 499-504 (For primary document see N93-24694 09-13)
Copyright Avail: CASI HC A02/MF A04

This paper provides a brief overview of the design considerations and the current status of the Miniature Optical Wide-Angle Lens Startracker Program. Mini-OWLS offers a revolutionary alternative to the conventional startracker. It is a small, lightweight, low cost, high performance startracker that can be used in a variety of applications including calibration and alignment of Inertial Measurement Units (IMU's) Mini-OWLS makes use of a strap down design incorporating Holographic Optical Elements (HOES) in place of conventional optics. HOES can be multiplexed so that the same aperture can be used for multiple separate optical paths looking in several directions simultaneously without startracker rotation. Additionally, separate Schmidt corrector plates are not required to compensate for spherical aberration. The optical assembly, or what would normally be considered as the telescope, is less than 20 cc in volume, weighs less than 55 grams, and contains the equivalent of three individual telescopes. Each one has a 4 deg Field of View (FOV) with a field of regard of 48 square degrees. Mini-OWLS has a bandwidth of approximately 300 nm in or near the visible wavelength. The projected resolution of the startracker is 5 to 10 arcseconds, depending on the centroiding algorithm used. The Mini-OWLS program was initiated last year and represents a miniaturized version of a similar design for aeronautical applications. The contract is managed by Wright Laboratory, Air Force Systems Command, Wright-Patterson AFB, Ohio, with funding from the Strategic Defense Initiative Organization through Eglin AFB. The initial phase of the program is to build and test a development unit. The second phase is to integrate the startracker with the Charles Stark Draper Laboratory Micromechanical Inertial Guidance System (MIGS) and the Signal Processing Packaging Design (SPPD) being developed by Texas Instruments. The preliminary design review was conducted in November 1991. Three-axes prototype telescope assemblies have been built and design evaluation tests initiated. Author

Attitude determination of spacecraft usually utilizes vector measurements such as Sun, center of Earth, star, and magnetic field direction to update the quaternion which determines the spacecraft orientation with respect to some reference coordinates in the three dimensional space. These measurements are usually processed by an extended Kalman filter (EKF) which yields an estimate of the attitude quaternion. Two EKF versions for quaternion estimation were presented in the literature; namely, the multiplicative EKF (MEKF) and the additive EKF (AEKF). In the multiplicative EKF, it is assumed that the error between the correct quaternion and its a-priori estimate is, by itself, a quaternion that represents the rotation necessary to bring the attitude which corresponds to the a-priori estimate of the quaternion into coincidence with the correct attitude. The EKF basically estimates this quotient quaternion and then the updated quaternion estimate is obtained by the product of the a-priori quaternion estimate and the estimate of the difference quaternion. In the additive EKF, it is assumed that the error between the a-priori quaternion estimate and the correct one is an algebraic difference between two four-tuple elements and thus the EKF is set to estimate this difference. The updated quaternion is then computed by adding the estimate of the difference to the a-priori quaternion estimate. If the quaternion estimate converges to the correct quaternion, then, naturally, the quaternion estimate has unity norm. This fact was utilized in the past to obtain superior filter performance by applying normalization to the filter measurement update of the quaternion. It was observed for the AEKF that when the attitude changed very slowly between measurements, normalization merely resulted in a faster convergence; however, when the attitude changed considerably between measurements, without filter tuning or normalization, the quaternion estimate diverged. However, when the quaternion estimate was normalized, the estimate converged faster and to a lower error than with tuning only. In last years, symposium we presented three new AEKF normalization techniques and we compared them to the brute force method presented in the literature. The present paper presents the issue of normalization of the MEKF and examines several MEKF normalization techniques. Author

The attitude matrix minimizing Wahba's loss function is computed directly by a method that is competitive with the fastest known algorithm for finding this optimal estimate. The method also provides an estimate of the attitude error covariance matrix. Analysis of the special case of two vector observations identifies those cases for which the TRIAD or algebraic method minimizes Wahba's loss function. Author

The Upper Atmospheric Research Satellite (UARS) requires a highly accurate knowledge of its attitude to accomplish its mission. Propagation of the attitude state using gyro measurements is not sufficient to meet the accuracy requirements, and must be supplemented by a observer/compensation process to correct for dynamics and observation anomalies. The process of amending the attitude state utilizes a well known method, the discrete Kalman Filter. This study is a sensitivity analysis of the discrete Kalman Filter as implemented in the UARS Onboard Computer (OBC). The stability of the Kalman Filter used in the normal on-orbit control mode within the OBC, is investigated for the effects of corrupted observations and nonlinear errors. Also, a statistical analysis on the residuals of the Kalman Filter is performed. These analysis is based on simulations using the UARS Dynamics Simulator (UARSDSIM) and compared against attitude requirements as defined by General Electric (GE). An independent verification of expected accuracies is performed using the Attitude Determination Error Analysis System (ADEAS). Author

Flight Dynamics Facility (FDF) responsibilities for calibration of Upper Atmosphere Research Satellite (UARS) sensors included alignment calibration of the fixed-head star trackers (FHST's) and the fine Sun sensor (FSS), determination of misalignments and scale factors for the inertial reference units (IRU's), determination of biases for the three-axis magnetometers (TAM's) and Earth sensor assemblies (ESA's), determination of gimbal misalignments of the Solar/Stellar Pointing Platform (SSPP), and field-of-view calibration for the FSS's mounted both on the Modular Attitude Control System (MACS) and on the SSPP. The calibrations, which used a combination of new and established algorithms, gave excellent results. Alignment calibration results markedly improved the accuracy of both ground and onboard Computer (OBC) attitude determination. SSPP calibration results allowed UARS to identify stars in the period immediately after yaw maneuvers, removing the delay required for the OBC to reacquire its fine pointing attitude mode. SSPP calibration considerably improved the pointing accuracy of the attached science instrument package. This paper presents a summary of the methods used and the results of all FDF UARS sensor calibration. Author

The single solar array on the Upper Atmosphere Research Satellite (UARS) is subjected to a thermal distortion when the spacecraft enters and exits the Earth's shadow. The distortion results in a torque that alters the spacecraft attitude. Due to the sudden nature of the attitude discontinuity, the effect has been termed 'thermal snap'. Thermal snap has also been experienced by Landsats 4 and 5. Analyses by the spacecraft builder addressed the impact of the resultant torque on the onboard control system. This paper discusses the results of comparisons between the predicted effects of thermal snap on UARS and actual attitude solutions from UARS telemetry data. In addition, this paper describes the characteristics of the thermal snap on UARS in terms of maximum displacement, solar beta angle, and solar array drive angle. Comparisons are made between the actual times of thermal snaps and the predicted spacecraft sunrise and sunset times. The effects of the UARS thermal snap are summarized and a general comment is made relating possible effects of thermal snap on other satellites. Also, an analysis of UARS attitude solutions that span periods of thermal snap was performed to determine whether the gyro sampling time of 1/8 second is sufficient to properly model the resulting spacecraft attitude without compromising the accuracy requirements. The results of this analysis are discussed. Author

The Upper Atmosphere Research Satellite (UARS) uses fixed-head star trackers (FHST's) and inertial reference units (IRU's) to determine and control its attitude. This combination of fine sensors results in attitude knowledge accuracies to better than 10 arc-seconds (1 sigma). UARS also has a variety of coarse attitude sensors on board: the three-axis magnetometer (TAM), the coarse Sun sensor (CSS), the fine Sun sensor (FSS), and the Earth sensor assembly (ESA). By comparing attitude solutions using coarse sensors with FHST-determined attitude solutions, estimates can be made of the accuracy of the coarse sensors. This paper presents the results of an analysis that compares attitude solutions using various combinations of UARS coarse attitude sensor data with FHST attitude solutions. Author

OPTIMAL COOPERATIVE POWER-LIMITED RENDEZVOUS Ph.D. Thesis
Victoria Lynn Coverstone-Carroll 1992 229 p
Avail: Univ. Microfilms Order No. DA9236436

Minimum-fuel rendezvous of two power-limited low-thrust spacecraft is investigated. Both vehicles are active and provide thrust to complete the rendezvous. Total propellant consumption is minimized. Two gravitational field models are investigated: the Clohessy-Wiltshire linearized field and the inverse-square field. Analytical solutions are obtained for the linearized gravity field. A direct method using direct collocation with nonlinear programming is used for the nonlinear problem. Solutions obtained are checked against the primer vector necessary conditions for optimality. The optimal solutions depend in a complicated way on the power-to-mass ratios of the two spacecraft, the initial conditions, and the specified transfer time. Propellant and terminal orbit constraints are also discussed.

OPTIMAL FINITE-THRUST TIME-BOUNDED DIRECT-ASCENT INTERCEPTION Ph.D. Thesis
James Reagle Downey 1992 178 p
Avail: Univ. Microfilms Order No. DA9305510

Minimum-time and maximum final mass solutions are obtained for the problem of direct-ascent interception, from an arbitrary launch point on the surface of the Earth, of a target in a circular orbit. The intercepting rocket is assumed to have finite, bounded thrust and is subject to aerodynamic forces including lift and drag. The effect of Earth rotation is included and an initial waiting period or coast arc prior to launch is allowed. The problem is formulated as an optimal control problem with the objective of determining the thrust magnitude, aerodynamic pointing angle (pitch and yaw), and thrust vectoring angle histories to accomplish the interception. The continuous optimal control problem is converted to a discrete nonlinear programming problem and direct collocation is used to find numerical solutions. Solutions are found for both time-open and time-fixed problems. Optimal solutions include both postgrade and retrograde intercept trajectories. Solutions are obtained for a range of target orbit radii, inclinations, launch points, and initial target locations relative to the launch points. Problems which may include a singular arc as part of the optimal trajectory are also considered, and a method is demonstrated which allows such problems to be solved using direct collocation. PROGRADE ANOMALOUS ORBITS IN TRIAXIAL GRAVITATIONAL POTENTIALS THAT ROTATE ABOUT THE LONG AXIS: VLA NEUTRAL HYDROGEN OBSERVATIONS AND MODELING OF THE INCLINED RINGS AROUND THE GALAXIES NGC 2685 AND NGC 660 Ph.D. Thesis
Mary Elaine Mahon 1992 201 p
Avail: Univ. Microfilms Order No.DA9304024

This dissertation presents the results of a systematic study of the inclined family of prograde anomalous orbits in rotating, triaxial gravitational potentials. In particular, for the case where the long axis of the potential is the rotation axis, the bifurcation sequence of orbits containing the prograde anomalous family is explored as a function of the rotation speed of the potential. Neutral hydrogen observations of the galaxies NGC 2685 and NGC 660 obtained with the Very Large Array Radio Telescope (VLA) are also presented. Maps derived from these observations show that both galaxies contain two kinematically distinct systems of gas, one in a nearly polar orientation, and the other approximately in the plane of the central stellar disk. If the underlying gravitational potential of the galaxy is triaxial and rotating, such configurations can be stable. It is shown that a model constructed from an ensemble of orbits, which contains the stable anomalous and prograde elliptical families, yields velocity and surface density maps similar to those derived from the VLA neutral hydrogen observations of NGC 2685 and NGC 660. The real interest of such a treatment is that, unlike the case for rotation about the short axis of the potential, it allows for the stars and gas in the disk of the central galaxy to rotate in the

same sense. These models indicate that for both NGC 2685 and NGC 660, the underlying gravitational potential is mildly triaxial and slowly rotating. An understanding of the shape of gravitational potential for these peculiar galaxies ultimately may lead to a better understanding of the three-dimensional distribution of matter in normal elliptical and spiral galaxies. ORBITAL PARAMETER ESTIMATION USING AN EXTENDED KALMAN FILTER Ph.D. Thesis
Daniel J. Brett Dec. 1992 108 p
(AD-A260618) Avail: CASI HC A06/MF A02

The problem of orbital parameter estimation using angles only observations is examined. Direction cosine measurements, obtained from satellite passage of an earth-based stationary planar radar beam, are assimilated by an extended Kalman filter to improve estimates of a classical orbital element set. Several progressively comprehensive orbital motion models are considered and compared. The relative effectiveness of these models is illustrated by applying them to actual satellite data. DTIC

MINIMUM-FUEL POWER-LIMITED TRANSFERS BETWEEN COPLANAR ELLIPTIC ORBITS Ph.D. Thesis
Christine Marie Haissig 1992 265 p
Avail: Univ. Microfilms Order No. DA9235255

Researchers have studied transfers for spacecraft using electric propulsion systems for many years. Previous work can be put into two categories--approximate results for restricted cases and numerical optimization results for specific missions or simple geometries. Approximate results exist for two limiting cases: many-revolution transfers with slowly changing orbit elements for which averaging applies and short duration transfers with small changes in the orbit elements for which linearization applies. Mission results are limited to transfers between circular orbits, as for the earth-Mars and earth-Venus missions, and escape problems. This research focuses on (1) the development of a systematic and accurate procedure for solving minimum-fuel, power limited transfers, and (2) the application of this procedure to characterize multiple revolution, minimum-fuel, power-limited transfers. The solution procedure is based on averaging. The adjoint from the average solution, referred to as the average adjoint, is the basis for two approximate solutions. In the first approximate solution the initial average adjoint serves as an estimate of the unknown initial adjoint. In the second approximation, the average adjoint is substituted into the minimum-fuel control law to provide an approximate optimal control. A canonical transformation is developed to transform the average adjoint from orbit element coordinates, which are used for averaging, to trajectory variable coordinates, which are used for numerical integration. These approximations are accurate for multiple revolution transfers. Their accuracy is inversely proportional to the transfer time, and transfers with extremely low or extremely high eccentricity are less accurate than those with moderate eccentricity for a given transfer time. The transformed adjoint from the average solution is used to generate the locally minimizing trajectories that are used in the characterization. Illustrative transfers are presented for many transfer times and transfer geometries. This characterization finds that (1) averaging qualitatively predicts the secular behavior of the semimajor axis and quantitatively predicts the eccentricity and argument of periapse for transfers with at least three revolutions; and (2) the linear theory qualitatively predicts the thrust magnitude and direction for an individual revolution given the secular predictions in the orbit elements.

OPTIMAL TRANSFERS BETWEEN LIBRATION-POINT ORBITS IN THE ELLIPTIC RESTRICTED THREE-BODY PROBLEM Ph.D. Thesis
Lisa Ann Hiday 1992 248 p
Avail: Univ. Microfilms Order No. DA9301310

A strategy is formulated to design optimal impulsive transfers between three-dimensional libration-point orbits in the vicinity of the interior L(1) libration point of the Sun-Earth/Moon barycenter system. Two methods of constructing nominal transfers, for which the fuel cost is to be minimized, are developed; both inferior and superior transfers between two halo orbits are considered. The necessary conditions for an optimal transfer trajectory are stated in terms of the primer vector. The adjoint equation relating reference and perturbed trajectories in this formulation of the elliptic restricted three-body problem is shown to be distinctly different from that obtained in the analysis of trajectories in the two-body problem. Criteria are established whereby the cost on a nominal transfer can be improved by the addition of an interior impulse or by the implementation of coastal arcs in the initial and final orbits. The necessary conditions for the local optimality of a time-fixed transfer trajectory possessing additional impulses are satisfied by requiring continuity of the Hamiltonian and the derivative of the primer vector at all interior impulses. The optimality of a time-free transfer containing coastal arcs is surmised by examination of the slopes at the endpoints of a plot of the magnitude of the primer vector over the duration of the transfer path. If the initial and final slopes of the primer magnitude are zero, the transfer trajectory is optimal; otherwise, the execution of coasts is warranted. The position and timing of each interior impulse applied to a time-fixed transfer as well as the direction and length of coastal periods implemented on a time-free transfer are specified by the unconstrained minimization of the appropriate variation in cost utilizing a multivariable search technique. Although optimal solutions in some instances are elusive, the time-fixed and time-free optimization algorithms prove to be very successful in diminishing costs on nominal transfer trajectories. The inclusion of coastal arcs on time-free superior and inferior transfers results in significant modification of the transfer time of flight caused by shifts in departure and arrival locations on the halo orbits. THEORETICAL AND EXPERIMENTAL INVESTIGATION OF ELECTRON BEAM ACCELERATION AND SUB-MILLIMETER WAVE GENERATION Final Report, 25 Jun. 1991 - 24 Jun. 1992
N. C. Luhmann, Jr. and D. B. McDermott Oct. 1992 76 p
(Contract DAAL03-91-G-0190)
(AD-A261117; ARO-28396.1-PH) Avail: CASI HC A05/MF A01

The overall objective of our research for ARO is to develop devices that have the potential for being compact generators of submillimeter-wave radiation. (1) The high-harmonic gyro-frequency multiplier, which is an efficient generator of high frequency RF, will be tested at the tenth-harmonic in our rebuilt test-stand. (2) High-power harmonic gyro-TWTs can be designed to operate in high order modes in large size waveguide by using the marginal stability design criterion. (3) Our high power, second-harmonic TE2 1 gyro-TWT, which is predicted to generate an order of magnitude higher power than state-of-the-art fundamental frequency gyrotrons, has been fully designed and construction is well underway. (4) The interaction strength in our high-harmonic CARM increases as the electron Larmor radius moves closer to the wall radius as the magnetic field is lowered towards a grazing intersection. (5) A high performance amplifier is predicted to result from our initial gyro-klystron experiment. DTIC

MODIFIED POINT MASS TRAJECTORY SIMULATION FOR BASE-BURN PROJECTILES Final Report, Sep. 1990 - Dec. 1991
R. F. Lieske and J. E. Danberg Mar. 1992 40 p
(DA Proj. 1L1-62618-AH-80)
(BRL-TR-3321) Avail: CASI HC A03/MF A01

An addition to the Modified Point Mass Trajectory Model for Rocket-Assisted Projectiles is presented for the exterior ballistic simulation of base-burn projectiles. The addition models the change in aerodynamic base-drag based on the change in base pressure due to the base-burn motor's ejection of hot gas into the wake of the projectile. The mass flow rate of the remaining fuel of the base-burn motor is modeled as a function of the instantaneous projectile spin rate and atmospheric air pressure. HAWK Doppler radar data collected at Yuma Proving Ground, Arizona, for the 155mm, M1864 base-burn projectile were used to verify the modeling approach for a variety of test conditions. NATIONAL LAUNCH SYSTEM. TASK 4: SYSTEM ARCHITECTURE OPTIONS ANALYSIS Final Technical Report
A. C. Palen 25 Aug. 1992 357 p
(Contract F04701-88-C-0109)
(MCR-92-5011; CDRL-103A-10) Avail: CASI HC A16/MF A03

Task 4 was defined to fulfill the requirements of the NLS contract Statement of Work (SOW) 3.2.2 - System Level Trades. The objective, approach, subtasks, and schedule outlined for Task 4 System Architecture Options Analysis are given. This Final Report provides the documentation for Task 4. The objective is to establish the system approach (mission and ground capability requirements) for using a modular family of vehicles and associated operations and information infrastructure to satisfy the range of mission requirements commensurate with non-recurring and recurring cost goals, commonality, operability needs, and the requirements for growth potential. Using Level 3 concept definition and outputs from other tasks, candidate concepts for the vehicle family and operations concepts are developed. Concepts developed versus requirements and constraints are assessed to develop a system architecture. Tasks performed include obtaining input data and output needs from Level 3; conducting architecture analysis versus traffic model, design constraints, ground rules and break points; assessing architecture sensitivities to uncertain parameters; and documenting results. NLS OPERATIONS CONCEPTS: FAILURE MODES SCENARIO SIMULATION MODEL ANALYSIS Supplemental Report
Kevin Brughelli and Jerry Andersen 30 Nov. 1992 17 p
(Contract F04701-88-C-0109)
(MCR-92-5013; CDRL-103A10) Avail: CASI HC A03/MF A01

As part of the NLS contract termination activity, a task to determine failure modes impacts on the NLS operations concepts and time line process flows was recommended and approved. This report summarizes that activity. This is a final report and no further analyses are planned. To date, most NLS operations studies and analyses have examined 'normal' process activity, without any granular analysis of failures and their impacts on the NLS mission. 'Maintenance loops' have been identified as logical places in the flow where a failure is likely to occur and generic ('vanilla') times have been allocated to these loops. The purpose of this top level analysis was to examine in some detail the disruption to the flow caused by failures, the impact of these failures on the process and the mission model, and various scenarios for returning the system to operational status following a failure. TASK 5: ARCHITECTURE SENSITIVITY TO STME PERFORMANCE Final Report
J. A. Schnackel 7 Sep. 1992 61 p
(Contract F04701-88-C-0109)
(MCR-92-5010; CDRL-103A10) Avail: CASI HC A04/MF A01

This document was prepared for Task 5: Architecture Sensitivity to Space Transportation Main Engine (STME) Performance. Information provided in this report documents the architecture sensitivities with respect to STME performance parameters. Suggested STME thrust level was driven by Task 5 sensitivities and Task 4 vehicle configurations. Recommendations on STME thrust level are presented in this report. Sensitivities to STME parameters and vehicle system parameters were evaluated. Design of Experiment (DOE) approaches were used to understand the relative importance of each parameter. Suggested sensitivity parameters and their respective ranges were provided to the Task 5 lead. Our recommendation on analysis approach for the sensitivities was a central composite faced design. Task 5 sensitivities should be updated following final Task 4 architecture recommendations. A suggested analysis approach is provided in the analysis section of this report (Part C, Appendix I, Analysis). This analysis approach was used on Advanced Launch System (ALS) Phase 2 to improve the evaluation of alternate engine designs and vehicle subsystem evaluations. It is suggested that the analysis approach outlined in Part C be utilized to update Task when final Task 4 architecture information is available. Contents of this submittal include: Part A, Narrative Summary; Part B, View Graphs with facing page text; Part C, Appendix I, Analysis Part C, Appendix II, Data. Author

(MCR-92-5006-Pt-A; CDRL-103A10) Avail: CASI HC A07/MF A02

This document was prepared as Task 2a: UNIS Requirements/Concept for the NLS Launch Management Control System (LMCS) Cross Functional Team (CFT). Data provided in this report is supplemented by the UNIS Information Model, copies of which are maintained and provided in a separate file and format with this submittal. This report reflects a compilation of inputs from LMCS CFT members who responded to our request for data. Where feasible, these inputs have been incorporated directly and/or conceptually. Reviewers are requested to consider the following: The results of this report may require additional analysis as NLS concepts mature or change. Terms and definitions used are frequently context sensitive and should be applied in the broadest sense, consistent with development of top level requirements and concepts. Transition to the next phase of NLS acquisition will generate more detailed and updated information system requirements analysis. Data contained in this report should be used for concept development and as input to the next phase of overall NLS system requirements analysis. Derived from text

DEVELOP MARGIN PHILOSOPHY TO ATTAIN ROBUSTNESS
D. G. Herbener 15 May 1992 27 p
(Contract F04701-88-C-0109)
(MCR-92-5005; CDRL-103A10) Avail: CASI HC A03/MF A01

This report is submitted to document the results of the study and evaluations associated with the task delineated as Margin Philosophy to Attain Robustness in Annex A to Attachment 9 of the National Launch Development Program Statement of Work dated September 30, 1991. Task no. 31, as defined in the SOW, is shown on Figure 1. In the process of conducting Sub Task 1, as defined on Figure 1, it became apparent that Robustness was not obtained by the management and/or control of margins but is the result of appropriate design philosophy used in the design and development of the total launch system. This total system must include all ground operations facilities, processes and support equipment as well as the launch vehicle and the processes and equipment associated with the production, handling and launch of the vehicle. The developed design philosophy must reflect a thorough understanding of design parameters, their potential interactions and how they are addressed during the design and analysis process. This task attempts to develop an approach, 'Design Philosophy to Attain Robustness', that may be applied to any launch vehicle system resulting in a Robust total system design. As a result of the above, the Objective, Approach and Sub Tasks for Task no. 31 have been changed to the following. Identify the launch system attributes required to develop a robust system. Identify the analyses and/or trade studies required to define the design philosophy necessary to attain the desired system Robustness. Derived from text

TASK TYPE E REPORT FOR NATIONAL LAUNCH DEMONSTRATION CENTER (NLDC) (TASK 32)
G. E. Elliot 13 Dec. 1991 69 p
(Contract F04701-88-C-0109)
(MCR-91-5010; CDRL-103A10) Avail: CASI HC A04/MF A01

The objective of this task was to define National Launch Demonstration Center (NLDC) requirements in support of National Launch System (NLS) Joint Program Office (JPO) Level 11 Task #32, NLDC Requirement Definition. The following document provided the basis for the study: Task authorization - Contract FO4701-88-C-0109, Modification P00025, SOW 3.2.11, Define NLDC Requirements. The Task was structured into the following series of activities: (1) identify NLS vehicle, operations, or information system requirements which could be demonstrated, integrated, validated, or verified using the NLDC; (2) establish groundrules and constraints for the NLDC; (3) develop a time phased approach for implementing the NLDC to match the NLS need dates and Spaceport Florida Authority/JPO funding availability; (4) support development of NLS JPO NLDC Plan; and (5) support development of NLS JPO NLDC Coordination Briefing. SPACE TRANSFER VEHICLE CONCEPTS AND REQUIREMENTS STUDY. VOLUME 1: EXECUTIVE SUMMARY Final Report, Aug. 1989 - Apr. 1991
Gary A. Weber Apr. 1991 101 p
(Contract NAS8-37855)
(NASA-CR-192524; NAS 1.26:192524; D180-32040-1-Vol-1) Avail: CASI HC A06/MF A02

A description of the study in terms of background, objectives, and issues is provided. NASA is currently studying new initiatives of space exploration involving both piloted and unpiloted missions to destinations throughout the solar system. Many of these missions require substantial improvements in launch vehicle and upper stage capabilities. This study provides a focused examination of the Space Transfer Vehicles (STV) required to perform these missions using the emerging national launch vehicle definition, the Space Station Freedom (SSF) definition, and the latest mission scenario requirements. The study objectives are to define preferred STV concepts capable of accommodating future exploration missions in a cost-effective manner, determine the technology development (if any) required to perform these missions, and develop a decision database of various programmatic approaches for the development of the STV family of vehicles. Special emphasis was given to examining space basing (stationing reusable vehicles at a space station), examining the piloted lunar mission as a primary design mission, and restricting trade studies to the high-performance, near-term cryogenics (LO2/LH2) as vehicle propellant. The study progressed through three distinct 6-month phases. The first phase concentrated on supporting a NASA 3 month definition of exploration requirements (the '90-day study') and during this phase developed and optimized the space-based point-of-departure (POD) 2.5-stage lunar vehicle. The second phase developed a broad decision database of 95 different vehicle options and transportation architectures. The final phase chose the three most cost-effective architectures and developed point designs to carry to the end of the study. These reference vehicle designs are mutually exclusive and correspond to different national choices about launch vehicles and in-space reusability. There is, however, potential for evolution between concepts. Author (revised)

During the 90-day study, support was provided to NASA in defining a point-of-departure space transfer vehicle (STV). The resulting STV concept was performance optimized with a two-stage LTV/LEV configuration. Appendix A reports on the effort during this period of the study. From the end of the 90-day study until the March Interim Review, effort was placed on optimizing the two-stage vehicle approach identified in the 90-day effort. After the March Interim Review, the effort was expanded to perform a full architectural trade study with the intent of developing a decision database to support STV system decisions in response to changing SEI infrastructure concepts. Several of the architecture trade studies were combined in a System Architecture Trade Study. In addition to this trade, system optimization/definition trades and analyses were completed and some special topics were addressed. Program- and system-level trade study and analyses methodologies and results are presented in this section. Trades and analyses covered in this section are: (1) a system architecture trade study; (2) evolution; (3) safety and abort considerations; (4) STV as a launch vehicle upper stage; and (5) optimum crew and cargo split. The Space Transfer Vehicle (STV) program provides both an opportunity and a requirement to increase our upper stage capabilities with the development and applications of new technologies. Issues such as man rating, space basing, reusability, and long lunar surface storage times drive the need for new technology developments and applications. In addition, satisfaction of mission requirements such as lunar cargo delivery capability and lunar landing either require new technology development or can be achieved in a more cost-effective manner with judicious applications of advanced technology. During the STV study, advanced technology development requirements and plans have been addressed by the Technology/Advanced Development Working Group composed of NASA and contractor representatives. This report discusses the results to date of this working group. The first section gives an overview of the technologies that have potential or required applications for the STV and identifies those technologies baselined for the STV. Figures are provided that list the technology categories and show the priority placed on those technology categories for either the space-based or ground-based options. The second section covers the plans and schedules for incorporating the technologies into the STV program. Author

This report presents the results of systems analyses and conceptual design of space transfer vehicles (STV). The missions examined included piloted and unpiloted lunar outpost support and spacecraft servicing, and unpiloted payload delivery to various earth and solar orbits. The study goal was to examine the mission requirements and provide a decision data base for future programmatic development plans. The final lunar transfer vehicles provided a wide range of capabilities and interface requirements while maintaining a constant payload mission model. Launch vehicle and space station sensitivity was examined, with the final vehicles as point design covering the range of possible options. Development programs were defined and technology readiness levels for different options were determined. Volume 1 presents the executive summary, volume 2 provides the study results, and volume 3 the cost and WBS data. Author

SPACE TRANSFER VEHICLE CONCEPTS AND REQUIREMENTS STUDY. VOLUME 3, BOOK 1: PROGRAM COST ESTIMATES Final Report, 1 Aug. 1989 - 1 Apr. 1991
Al F. Peffley 1 Apr. 1991 154 p
(Contract NAS8-37855)
(NASA-CR-192529; NAS 1.26:192529; D180-32040-3-Vol-3-Bk-1) Avail: CASI HC A08/MF A02

The Space Transfer Vehicle (STV) Concepts and Requirements Study cost estimate and program planning analysis is presented. The cost estimating technique used to support STV system, subsystem, and component cost analysis is a mixture of parametric cost estimating and selective cost analogy approaches. The parametric cost analysis is aimed at developing cost-effective aerobrake, crew module, tank module, and lander designs with the parametric cost estimates data. This is accomplished using cost as a design parameter in an iterative process with conceptual design input information. The parametric estimating approach segregates costs by major program life cycle phase (development, production, integration, and launch support). These phases are further broken out into major hardware subsystems, software functions, and tasks according to the STV preliminary program work breakdown structure (WBS). The WBS is defined to a low enough level of detail by the study team to highlight STV system cost drivers. This level of cost visibility provided the basis for cost sensitivity analysis against various design approaches aimed at achieving a cost-effective design. The cost approach, methodology, and rationale are described. A chronological record of the interim review material relating to cost analysis is included along with a brief summary of the study contract tasks accomplished during that period of review and the key conclusions or observations identified that relate to STV program cost estimates. The STV life cycle costs are estimated on the proprietary parametric cost model (PCM) with inputs organized by a project WBS. Preliminary life cycle schedules are also included. CASI

STS-39 SPACE SHUTTLE MISSION REPORT
Robert W. Fricke Jun. 1991 34 p Sponsored by NASA. Lyndon B. Johnson Space Center
(NASA-CR-193063; NAS 1.26:193063; JSC-08250) Avail: CASI HC A03/MF A01

The STS-39 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem operations during the fortieth flight of the Space Shuttle and the twelfth flight of the Orbiter Vehicle Discovery (OV-103). In addition to the Discovery vehicle, the flight vehicle consisted of the following: an External Tank (ET) (designated as ET-46 (LWT-39); three Space Shuttle main engines (SSME's) (serial numbers 2026, 2030, and 2029 in positions 1, 2, and 3, respectively); and two Solid Rocket Boosters (SRB's) designated as BI-043. The primary objective of this flight was to successfully perform the planned operations of the Infrared Background Signature Survey (IBSS),

Air Force Payload (AFP)-675, Space Test Payload (STP)-1, and the Multipurpose Experiment Canister (MPEC) payloads. Author (revised)

STS-37 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke May 1991 32 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193062; NAS 1.26:193062; JSC-08249) Avail: CASI HC A03/MF A01

The STS-37 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem activities during this thirty-ninth flight of the Space Shuttle and the eighth flight of the Orbiter Vehicle Atlantis (OV-104). In addition to the Atlantis vehicle, the flight vehicle consisted of the following: an External Tank (ET) (designated as ET-37/LWT-30); three Space Shuttle main engines (SSME's) (serial numbers 2019, 2031, and 2107 in positions 1, 2, and 3, respectively); and two Solid Rocket Boosters (SRB's) designated as BI-042. The primary objective of this flight was to successfully deploy the Gamma Ray Observatory (GRO) payload. The secondary objectives were to successfully perform all operations necessary to support the requirements of the Protein Crystal Growth (PCG) Block 2 version, Radiation Monitoring Experiment-3 (RME-3), Ascent Particle Monitor (APM), Shuttle Amateur Radio Experiment-2 (SAREX-2), Air Force Maui Optical Site Calibration Test (AMOS), Bioserve Instrumentation Technology Associates Materials Dispersion Apparatus (BIMDA), and the Crew and Equipment Transfer Aids (CETA) payloads. STS-43 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Sep. 1991 34 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193064; NAS 1.26:193064; NSTS-08252) Avail: CASI HC A03/MF A01

The STS-43 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem operations during the forty-second flight of the Space Shuttle Program and the ninth flight of the Orbiter Vehicle Atlantis (OV-104). In addition to the Atlantis vehicle, the flight vehicle consisted of the following: an External Tank (ET) designated as ET-47 (LWT-40); three Space Shuttle main engines (SSME's) (serial numbers 2024, 2012, and 2028 in positions 1, 2, and 3, respectively); and two Solid Rocket Boosters (SRB's) designated as BI-045. The primary objective of the STS-43 mission was to successfully deploy the Tracking and Data Relay Satellite-E/Inertial Upper Stage (TDRS-E/IUS) satellite and to perform all operations necessary to support the requirements of the Shuttle Solar Backscatter Ultraviolet (SSBUV) payload and the Space Station Heat Pipe Advanced Radiator Element (SHARE-2). STS-40 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Jul. 1991 34 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-TM-108737; NAS 1.15:108737; NSTS-08251) Avail: CASI HC A03/MF A01

The STS-40 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem operations during the forty-first flight of the Space Shuttle and the eleventh flight of the Orbiter Vehicle Columbia (OV-102). In addition to the Columbia vehicle, the flight vehicle consisted of an External Tank (ET) designated as ET-41 (LWT-34), three Space Shuttle main engines (SSME's) (serial numbers 2015, 2022, and 2027 in positions 1, 2, and 3, respectively), and two Solid Rocket Boosters (SRB's) designated as BI-044. The primary objective of the STS-40 flight was to successfully perform the planned operations of the Spacelab Life Sciences-1 (SLS-1) payload. The secondary objectives of this flight were to perform the operations required by the Getaway Special (GAS) payloads and the Middeck O-Gravity Dynamics Experiment (MODE) payload. Author (revised)

STS-45 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke May 1992 34 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193054; NAS 1.26:193054; NSTS-08275) Avail: CASI HC A03/MF A01

The STS-45 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem operations during the forty-sixth flight of the Space Shuttle Program and the eleventh flight of the Orbiter Vehicle Atlantis (OV-104). In addition to the Atlantis vehicle, the flight vehicle consisted of the following: an External Tank (ET) designated as ET-44 (LWT-37); three Space Shuttle main engines (SSME's), which were serial numbers 2024, 2012, and 2028 in positions 1, 2, and 3, respectively; and two Solid Rocket Boosters (SRB's) designated as BI-049. The lightweight redesigned Solid Rocket Motors (RSRM's) installed in each of the SRB's were designated as 360L021A for the left SRM and 360W021B for the right SRM. The primary objective of this mission was to successfully perform the planned operations of the Atmospheric Laboratory for Applications and Science-1 (ATLAS-1) and the Shuttle Solar Backscatter Ultraviolet Instrument (SSBUV) payloads. The secondary objectives were to successfully perform all operations necessary to support the requirements of the following: the Space Tissue Loss-01 (STL-01) experiment; the Radiation Monitoring Equipment-3 (RME-3) experiment; the Visual Function Tester-2 (VFT-2) experiment; the Cloud Logic to Optimize use of Defense System (CLOUDS-1A) experiment; the Shuttle Amateur Radio Experiment 2 (SAREX-2) Configuration B; the Investigation into Polymer Membranes Processing experiment; and the Get-Away Special (GAS) payload G-229. The Ultraviolet Plume Instrument (UVPI) was a payload of opportunity that required no special maneuvers. In addition to the primary and secondary objectives, the crew was tasked to perform as many as 10 Development Test Objectives (DTO'S) and 14 Detailed Supplementary Objectives (DSO's). STS-47 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke, Jr. Oct. 1992 38 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193056; NAS 1.26:193056; NSTS-08279) Avail: CASI HC A03/MF A01

The STS-47 Space Shuttle Program Mission Report provides a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle main engine (SSME) subsystem performance during the fiftieth Space Shuttle Program flight and the second flight of the Orbiter Vehicle Endeavour (OV-105). In addition to the Endeavour vehicle, the flight vehicle consisted of the following: an ET which was designated ET-45 (LWT-38); three SSME's which were serial numbers 2026, 2022, and 2029 and were located in positions 1, 2, and 3, respectively; and two SRB's which were designated BI-053. The lightweight/redesigned RSRM that was installed in the left SRB was designated 360L026A, and the RSRM that was installed in the right SRB was 360W026B. The primary objective of the STS-47 flight was to successfully perform the planned operations of the Spacelab-J (SL-J) payload (containing 43 experiments--of which 34 were provided by the Japanese National Space Development Agency (NASDA)). The secondary objectives of this flight were to perform the operations of the Israeli Space Agency Investigation About Hornets (ISAIAH) payload, the Solid Surface Combustion Experiment (SSCE), the Shuttle Amateur Radio Experiment-2 (SAREX-2), and the Get-Away Special (GAS) payloads. The Ultraviolet Plume Instrument (UVPI) was flown as a payload of opportunity. Author (revised)

STS-44 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Jan. 1992 32 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-TM-108735; NAS 1.15:108735; NSTS-08273) Avail: CASI HC A03/MF A01

The STS-44 Space Shuttle Program Mission Report is a summary of the vehicle subsystem operations during the forty-fourth flight of the Space Shuttle Program and the tenth flight of the Orbiter vehicle Atlantis (OV-104). In addition to the Atlantis vehicle, the flight vehicle consisted of the following: an External Tank (ET) designated as ET-53 (LWT-46); three Space Shuttle main engines (SSME's) (serial numbers 2015, 2030, and 2029 in positions 1, 2, and 3, respectively); and two Solid Rocket Boosters (SRB's) designated

as BI-047. The lightweight redesigned Solid Rocket Motors (RSRM's) installed in each one of the SRB's were designated as 360L019A for the left SRB and 360W019B for the right SRB. The primary objective of the STS-44 mission was to successfully deploy the Department of Defense (DOD) Defense Support Program (DSP) satellite/inertial upper stage (IUS) into a 195 nmi. earth orbit at an inclination of 28.45 deg. Secondary objectives of this flight were to perform all operations necessary to support the requirements of the following: Terra Scout, Military Man in Space (M88-1), Air Force Maui Optical System Calibration Test (AMOS), Cosmic Radiation Effects and Activation Monitor (CREAM), Shuttle Activation Monitor (SAM), Radiation Monitoring Equipment-3 (RME-3), Visual Function Tester-1 (VFT-1), and the Interim Operational Contamination Monitor (IOCM) secondary payloads/experiments. STS-42 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Feb. 1992 32 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193059; NAS 1.26:193059; NSTS-08274) Avail: CASI HC A03/MF A01

The STS-42 Space Shuttle Program Mission Report contains a summary of the vehicle subsystem operations during the forty-fifth flight of the Space Shuttle Program and the fourteenth flight of the Orbiter vehicle Discovery (OV-103). In addition to the Discovery vehicle, the flight vehicle consisted of the following: an External Tank (ET) designated as ET-52 (LWT-45); three Space Shuttle main engines (SSME's), which were serial numbers 2026, 2022, and 2027 in positions 1, 2, and 3, respectively; and two Solid Rocket Boosters (SRB's) designated as BI-048. The lightweight redesigned Solid Rocket Motors (RSRM's) installed in each one of the SRB's were designated as 360L020A for the left SRM and 360Q020B for the right SRM. The primary objective of the STS-42 mission was to complete the objectives of the first International Microgravity Laboratory (IML-1). Secondary objectives were to perform all operations necessary to support the requirements of the following: Gelation of Sols: Applied Microgravity Research (GOSAMR); Student Experiment 81-09 (Convection in Zero Gravity); Student Experiment 83-02 (Capillary Rise of Liquid Through Granular Porous Media); the Investigation into Polymer Membrane Processing (IPMP); the Radiation Monitoring Equipment-3 (RME-3); and Get-Away Special (GAS) payloads carried on the GAS Beam Assembly. STS-46 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Oct. 1992 34 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193058; NAS 1.26:193058; NSTS-08278) Avail: CASI HC A03/MF A01

The STS-46 Space Shuttle Program Mission Report contains a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle main engine (SSME) subsystem performance during the forty-ninth flight of the Space Shuttle Program, and the twelfth flight of the Orbiter vehicle Atlantis (OV-104). In addition to the Atlantis vehicle, the flight vehicle consisted of the following: an ET, designated ET-48 (LWT-41); three SSME's, which were serial numbers 2032, 2033, and 2027 in positions 1, 2, and 3, respectively; and two SRB's which were designated BI-052. The lightweight/redesigned SRM's that were installed in each SRB were designated 360W025A for the left RSRM and 360L025B for the right RSRM. The primary objective of this flight was to successfully deploy the European Retrievable Carrier (EURECA) payload and perform the operations of the Tethered Satellite System-1 (TSS-1) and the Evaluation of Oxygen Interaction with Material 3/Thermal Energy Management Processes 2A-3 (EOIM-3/TEMP 2A-3). The secondary objectives of this flight were to perform the operations of the IMAX Cargo Bay Camera (ICBC), Consortium for Material Development in Space Complex Autonomous Payload-2 and 3 (CONCAP-2 and CONCAP-3), Limited Duration Space Environment Candidate Materials Exposure (LDCE), Pituitary Growth Hormone Cell Function (PHCF), and Ultraviolet Plume Instrumentation (UVPI). In addition to summarizing subsystem performance, this report also discusses each Orbiter, ET, SSME, SRB, and RSRM in-flight anomaly in the applicable section of the report. Also included in the discussion is a reference to the assigned tracking number as published on the Problem Tracking List. All times are given in Greenwich mean time (G.m.t.) as well as mission elapsed time (MET). Author (revised)

STS-50 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke Aug. 1992 43 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193057; NAS 1.26:193057; NSTS-08277) Avail: CASI HC A03/MF A01

The STS-50 Space Shuttle Program Mission Report contains a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle main engine (SSME) subsystem performance during the forty-eighth flight of the Space Shuttle Program, and the twelfth flight of the Orbiter vehicle Columbia (OV-102). In addition to the Columbia vehicle, the flight vehicle consisted of the following: an ET which was designated ET-50 (LUT-43); three SSME's which were serial numbers 2019, 2031, and 2011 in positions 1, 2, and 3, respectively; and two SRB's which were designated BI-051. The lightweight/redesigned RSRM's installed in each SRB were designated 360L024A for the left RSRM and 360M024B for the right RSRM. The primary objective of the STS-50 flight was to successfully perform the planned operations of the United States Microgravity Laboratory (USML-1) payload. The secondary objectives of this flight were to perform the operations required by the Investigations into Polymer Membrane Processing (IPMP), and the Shuttle Amateur Radio Experiment 2 (SAREX-2) payloads. An additional secondary objective was to meet the requirements of the Ultraviolet Plume Instrument (UVPI), which was flown as a payload of opportunity. Author (revised)

STS-52 SPACE SHUTTLE MISSION REPORT

Robert W. Fricke, Jr. Dec. 1992 44 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-193061; NAS 1.26:193061; NSTS-08280) Avail: CASI HC A03/MF A01

The STS-52 Space Shuttle Program Mission Report provides a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle main engine (SSME) subsystem performance during the fifty-first flight of the Space Shuttle Program, and the thirteenth flight of the Orbiter vehicle Columbia (OV-102). In addition to the Orbiter, the flight vehicle consisted of the following: an ET (designated as ET-55/LWT-48); three SSME's, which were serial numbers 2030, 2015, and 2034 in positions 1, 2, and 3, respectively; and two SRB's, which were designated BI-054. The lightweight RSRM's that were installed in each SRB were designated 360L027A for the left SRB and 360Q027B for the right SRB. The primary objectives of this flight were to successfully deploy the Laser Geodynamic Satellite (LAGEOS-2) and to perform operations of the United States Microgravity Payload-1 (USMP-1). The secondary objectives of this flight were to perform the operations of the Attitude Sensor Package (ASP), the Canadian Experiments-2 (CANEX-2),

the Crystals by Vapor Transport Experiment (CVTE), the Heat Pipe Performance Experiment (HPP), the Commercial Materials Dispersion Apparatus Instrumentation Technology Associates Experiments (CMIX), the Physiological System Experiment (PSE), the Commercial Protein Crystal Growth (CPCG-Block 2), the Shuttle Plume Impingement Experiment (SPIE), and the Tank Pressure Control Experiment (TPCE) payloads.

ASSURED CREW RETURN VEHICLE MAN-SYSTEMS INTEGRATION STANDARDS
Jul. 1991 323 p
(NASA-CR-193065; NAS 1.26:193065; NASA-STD-3000-Vol-6) Avail: CASI HC A14/MF A03

This is Volume 6 of the Man-Systems Integration Standards (MSIS) family of documents, which is contained in several volumes and a relational database. Each volume has a specific purpose, and each has been assembled from the data contained in the relational database. Volume 6 serves as the Assured Crew Return Vehicle project man-systems integration design requirements. The data in this document is a subset of the data found in Volume 1 and defines the requirements which are pertinent to the Assured Crew Return Vehicle as defined in the SPRD. Additional data and guidelines are provided to assist in the design.

(NASA-TM-108752; NAS 1.15:108752; JSC-25458) Avail: CASI HC A04/MF A01

Rendezvous, Proximity Operations, and Capture (RPOC) is a missions operations area which is extremely important to present and future space initiatives and must be well planned and coordinated. To support this, a study team was formed to identify a specific plan of action using the Quality Function Deployment (QFD) process. This team was composed of members from a wide spectrum of engineering and operations organizations which are involved in the RPOC technology area. The key to this study's success is an understanding of the needs of potential programmatic customers and the technology base available for system implementation. To this end, the study team conducted interviews with a variety of near term and future programmatic customers and technology development sponsors. The QFD activity led to a thorough understanding of the needs of these customers in the RPOC area, as well as the relative importance of these needs.

Experiments conducted in spacecraft and drop towers show that thin-sheet materials have reduced flammability ranges and flame-spread rates under quiescent low-gravity environments (microgravity) as compared to normal gravity. Furthermore, low-gravity flames may be suppressed more easily by atmospheric dilution or decreasing atmospheric total pressure than their normal-gravity counterparts. The addition of a ventilating air flow to the low-gravity flame zone, however, can greatly enhance the flammability range and flame spread. These results, along with observations of flame and smoke characteristics useful for microgravity fire-detection 'signatures', promise to be of considerable value to spacecraft fire-safety designs. The

paper summarizes the fire detection and suppression techniques proposed for the Space Station Freedom and discusses both the application of low-gravity combustion knowledge to improve fire protection and the critical needs for further research. Author (revised)

DYNAMICS AND CONTROL OF MANEUVERABLE TETHERED FLIGHT VEHICLES Ph.D. Thesis
Tae Soo No 1992 171 p
Avail: Univ. Microfilms Order No. DA9237200

Problems concerning the dynamics and control of tethered flight vehicles (TFV) are addressed. These tethered systems include towed vehicle systems (TVS), tethered satellite systems (TSS) and tethered hypervelocity vehicles (THV). Rather general equations of motion are obtained. These are valid for three operational modes: deployment, station-keeping and retrieval. A computer simulation program based on the general equations of motion is used to investigate the dynamics and control of these types of systems. Stability characteristics of various TFV's are extensively investigated both numerically and analytically. It is found that the addition of attitude dynamics of an end body causes significant differences in the stability characteristics of both the THV and the TSS. It is also shown, via nonlinear simulation, that the perturbed motion of a TVS about an unstable equilibrium state approaches a stable limit cycle. The use of a simple physical model of a TFV in the design of a feedback control system is justified. Linear optimal control theory is used to synthesize control laws for station-keeping and maneuvers of the tethered vehicle. The rotational motion of the end body is well controlled during station-keeping and maneuvers. It is shown that under appropriate circumstances, aerodynamic control is a viable alternative to reaction (thruster) control. Dissert. Abstr.

This work presents tables to assist in the evaluation of pinhole collection effects on spacecraft. These tables summarize results of a computer model which tracks particle trajectories through a simplified electric field in the plasma sheath. A technique is proposed to account for plasma sheath effects in the application of these results and scaling rules are proposed to apply the calculations to specific situations. This model is compared to ion current measurements obtained by another worker, and the agreement is very good. Author

UARS IN-FLIGHT JITTER STUDY FOR EOS Final Report
John Molnar and Mike Garnek Jan. 1993 199 p
(Contract NAS5-32500; RTOP 585-03-11-01)
(NASA-CR-191419; NAS 1.26:191419) Avail: CASI HC A09/MF A03

Response data collected from gyroscopes on board the Upper Atmosphere Research Satellite (UARS) provided a unique opportunity to analyze actual flight pointing jitter data. Flight modal frequencies and damping values are derived from the measured data using an Eigensystem Realization Algorithm (ERA). Flight frequencies at various solar array positions are compared to analytical predictions obtained with a Finite Element Model. The solar array modal frequencies change with position due to the modes acting about different spacecraft inertial axes. Higher order modes were difficult to identify due to the limited instrumentation. Future flight jitter studies on other spacecraft would be significantly aided by additional instrumentation. Spacecraft jitter due to continuous disturbance sources such as the 1.6 meter scanning microwave antenna, the solar array drive, and reaction wheels is presented. The solar array drive disturbance dominates the spacecraft response during normal operation. Author

SPACE STATION FREEDOM ASSEMBLY AND OPERATION AT A 51.6 DEGREE INCLINATION ORBIT
Patrick A. Troutman, Laura M. Brewer (Analytical Mechanics Associates, Inc., Hampton, VA.), Michael L. Heck (Analytical Mechanics Associates, Inc., Hampton, VA.), and Renjith R. Kumar (Analytical Mechanics Associates, Inc., Hampton, VA.) Jan. 1993 34 p
(RTOP 476-14-15-01)
(NASA-TM-107731; NAS 1.15:107731) Avail: CASI HC A03/MF A01

This study examines the implications of assembling and operating Space Station Freedom at a 51.6 degree inclination orbit utilizing an enhanced lift Space Shuttle. Freedom assembly is currently baselined at a 220 nautical mile high, 28.5 degree inclination orbit. Some of the reasons for increasing the orbital inclination are (1) increased ground coverage for Earth observations, (2) greater accessibility from Russian and other international launch sites, and (3) increased number of Assured Crew Return Vehicle (ACRV) landing sites. Previous studies have looked at assembling Freedom at a higher inclination using both medium and heavy lift expendable launch vehicles (such as Shuttle-C and Energia). The study assumes that the shuttle is used exclusively for delivering the station to orbit and that it can gain additional payload capability from design changes such as a lighter external tank that somewhat offsets the performance decrease that occurs when the shuttle is launched to a 51.6 degree inclination orbit. MANEUVERING A REENTRY BODY VIA MAGNETO-GASDYNAMIC FORCES Ph.D. Thesis
Leo Patrick OHare 1992 171 p
Avail: Univ. Microfilms Order No. DA9304370

Some of the characteristics of the interaction of an electrically conducting fluid with a non-uniform applied magnetic field and a potential magnetogasdynamic control system which may be used on future aerospace vehicles are presented. The flow through a two dimensional channel is predicted by numerically solving the magnetogasdynamic equations using a time marching technique. The fluid was modeled as a compressible, inviscid, supersonic gas with finite electrical conductivity. Development of the algorithm provided a means to predict and analyze phenomena associated with magnetogasdynamic flows which had not been previously explored using numerical methods. One such phenomena was the prediction of oblique waves resulting from the interaction of an electrically conducting fluid with a non-uniform applied magnetic field. Development of this tool provided a means to explore an application which might have potential use for future aerospace vehicle missions. In order to appreciate the significance of this technology, predictions were made of the pitching moment about a slender blunted cone, generated by a system relying on the fluid-magnetic interaction. These moments were compared to predictions of a pitching moment generated by a deflecting control surface on the same vehicle. It was shown that the proposed magnetogasdynamic system could produce moments which were on the same order as the moments produced by the flap systems at low deflection angles. Dissert. Abstr.

CEOS COMMITTEE ON EARTH OBSERVATIONS SATELLITES CONSOLIDATED REPORT, 1992
1992 68 p Presented at the 6th CEOS Plenary, London, England, 9-11 Dec. 1992
(NASA-TM-108776; NAS 1.15:108776) Avail: CASI HC A04/MF A01

A concise overview of the committee on Earth Observations Satellites (CEOS) and its Working Groups, covering the history and purpose of the Committee and its accomplishments to date are provided. The report will be updated annually before each Plenary meeting, and as developments in the Working Groups warrant. The committee on Earth Observations Satellites (originally named the International Earth Observations Satellite committee, IEOS) was treated in 1984, in response to a recommendation from the Economic Summit of Industrialized Nations Working Group on Growth, Technology, and Employment's Panel of Experts on Satellite Remote Sensing. This group recognized the multidisciplinary nature of satellite Earth observations, and the value of coordinating across all proposed missions. Thus, CEOS combined the previously existing groups for coordination on Ocean Remote-Sensing Satellites (CORSS) and coordination on Land

Remote-Sensing Satellites (CLRSS), and established a broad framework for coordination across all spaceborne Earth observations missions. The first three LEOS Plenary meetings focused on treating and guiding the Working Groups deemed necessary to carry out the objectives of the CEOS members. After the third meeting, it was agreed that a more active orientation was required by the Plenary, and additional issues were brought before the group at the fourth meeting. At the fifth Plenary, international scientific programs and relevant intergovernmental organizations accepted invitations and participated as affiliate members of CEOS. This enabled progress toward integrating satellite data users' requirements into the CEOS process. Data exchange principles for global change research were also adopted. An interim CEOS Plenary meeting was held in April 1992, in preparation for the United Nations Conference on Environment and Development (UNCED). Brief encapsulations of the Plenary sessions immediately follow the Terms of Reference that govern the activities of CEOS as a whole; Terms of Reference for the individual Working Groups are included as Appendix A. A complete listing of CEOS members is offered as Appendix B. Author (revised)

TETHERED SATELLITE SYSTEM CONTINGENCY INVESTIGATION BOARD Final Report

6 Nov. 1992 51 p

(NASA-TM-108704; NAS 1.15:108704) Avail: CASI HC A04/MF A01

The Tethered Satellite System (TSS-1) was launched aboard the Space Shuttle Atlantis (STS-46) on July 31, 1992. During the attempted on-orbit operations, the Tethered Satellite System failed to deploy successfully beyond 256 meters. The satellite was retrieved successfully and was returned on August 6, 1992. The National Aeronautics and Space Administration (NASA) Associate Administrator for Space Flight formed the Tethered Satellite System (TSS-1) Contingency Investigation Board on August 12, 1992. The TSS-1 Contingency Investigation Board was asked to review the anomalies which occurred, to determine the probable cause, and to recommend corrective measures to prevent recurrence. The board was supported by the TSS Systems Working group as identified in MSFC-TSS-11-90, 'Tethered Satellite System (TSS) Contingency Plan'. The board identified five anomalies for investigation: initial failure to retract the U2 umbilical; initial failure to flyaway; unplanned tether deployment stop at 179 meters; unplanned tether deployment stop at 256 meters; and failure to move tether in either direction at 224 meters. Initial observations of the returned flight hardware revealed evidence of mechanical interference by a bolt with the level wind mechanism travel as well as a helical shaped wrap of tether which indicated that the tether had been unwound from the reel beyond the travel by the level wind mechanism. Examination of the detailed mission events from flight data and mission logs related to the initial failure to flyaway and the failure to move in either direction at 224 meters, together with known preflight concerns regarding slack tether, focused the assessment of these anomalies on the upper tether control mechanism. After the second meeting, the board requested the working group to complete and validate a detailed integrated mission sequence to focus the fault tree analysis on a stuck U2 umbilical, level wind mechanical interference, and slack tether in upper tether control mechanism and to prepare a detailed plan for hardware inspection, test, and analysis including any appropriate hardware disassembly. IDENTIFICATION AND CONTROL OF LIGHTLY DAMPED, LARGE SPACE STRUCTURES: AN EXPERIMENTAL EVALUATION Ph.D. Thesis

Joel Lea Berg 1992 292 p

Avail: Univ. Microfilms Order No. DA9237137

This dissertation concentrates on the three principal problems facing experimentalists during their attempts to identify and control lightly damped, large space structures (LSS). The problems are low damping, high modal density, and low natural frequencies of oscillation. They present a blend of difficulties which lead the experimentalist to turn to multiple-input multiple-output (MIMO) identification techniques and high performance compensators. Presented here are two MIMO modal identification techniques: Polyreference, and the Eigensystem Realization Algorithm, as well as two types of compensator-based controllers: Linear Quadratic Gaussian, and Independent Modal Space Control. The various techniques are described in the context of controlling lightly damped LSS. Because the research in this dissertation is primarily applications oriented, problems which experimentalists encounter in the laboratory are addressed as well as the performance of the different identification and control techniques on the test articles. Polyreference and ERA are both shown to perform very well in identifying modal frequencies while overestimating model damping ratios. Simulations show that high modal density combined with noisy data results in standard deviations that increase linearly with respect to mode separation. Pseudo-Inverse IMSC is shown to be robust with respect to system uncertainties. Block Independent Control is shown to possess minor coupling between blocks and provides a powerful control approach to overcome actuator bandwidth limitations. Dissert. Abstr.

NUMERICAL AND EXPERIMENTAL ANALYSES OF LARGE COMPOSITE SKELETAL SATELLITE SYSTEMS Ph.D. Thesis

D. A. C. Sparry 1992 287 p

Avail: Univ. Microfilms Order No. BRDX98135

The world's ever increasing demand for communication capacity has been the catalyst for the development of a range of next generation satellite reflectors. This new generation of satellites is significantly larger than those currently in orbit. Their dimensions prohibit transportation into space in their operational configuration. The use of deployable tetrahedral trusses for the reflecting surface support structures of a 50 m diameter Land Mobile Communication System is investigated. A deployable structural system was selected ahead of other possible forms, as it satisfied the majority of the criteria of low part count, quick assembly times, and an economical packaging volume thereby minimizing transportation and on-orbit fabrication costs. The composite material examined is formed from a polyethersulphone thermoplastic matrix reinforced with high strength, low modulus carbon fibers, C-PES. The modal characteristics of a series of scaled sub-units of the proposed structure were examined. These units, manufactured from the two types of material considered, C-PES and Perspex, were subjected to a range of excitation functions. The C-PES units were thermally cycled under high vacuum to simulate the space environment. The accelerated thermal cycling of the composite structural units revealed that a shift in resonant frequency occurred, together with some surface cracking which could affect the long term stability of the material. The effects of surface pigmentation on the thermal response were also considered. An algorithm was developed which allows low cost materials to be used to predict the behavior of geometrically similar units manufactured from the composite material. The interaction between the predicted dynamic structural behavior and the electrical performance of the satellite is also addressed and suggests that some form of active control system will be required if the maximum defocus parameter is not to be violated.

Dissert. Abstr.

AN ALTERNATE APPROACH TO SPACE MISSIONS INVOLVING A LONG TETHER Ph.D. Thesis

Ehud Netzer 1992 226 p

Avail: Univ. Microfilms Order No. DA9234138

Uses of tethers for a variety of purposes in space have been investigated extensively for many years. Currently, interest is focused on two NASA missions, TSS-1 and TSS-2, in which, a satellite is to be deployed, by means of a tether, from the Shuttle, and performs a series of experiments. The tethers to be used in TSS-1 and TSS-2 are very long, namely 20 km and 100 km, respectively. Hence, significant problems of dynamics and control arise in connection with all mission phases, and it is not yet clear that all of these problems possess satisfactory solutions. This must be a source of concern, given the fact that TSS-1 and TSS-2 are manned missions involving the very valuable Shuttle. It is the purpose of this dissertation to propose alternative means to accomplish the goals of missions such as those of TSS-1 and TSS-2, a way that involves the Shuttle and astronauts either minimally or not at all. Stated most simply, the proposal is this: replace the Shuttle with an unmanned spacecraft. Although this idea was mentioned in early papers on tethered systems, its feasibility remained to be investigated. A comprehensive study of such a system is the topic of the present dissertation. The system is composed of a primary satellite, a tether, and a secondary satellite. The primary satellite carries scientific instruments, whereas the secondary one is equipped with a set of thrusters for purposes of control. First, a 3D model, in which the tether is represented by two segments, is analyzed. Thereafter, multi-segment

models for the tether are considered; only part of the system states are measured, and the other states are estimated by means of a reduced order estimator. To optimize the deployment and retrieval phases, a multi-controller, MATLAB based algorithm, is employed. The result is improved performance and a significant reduction in fuel consumption. Finally, to use electrodynamic forces for orbit transfer without exciting tether bending motions, the notion of synchronized impulses, that is, running electric current through the tether at pre-calculated instants and amplitudes, is presented. Dissert. Abstr.

N93-25494# Lawrence Livermore National Lab., CA.
EXPERIMENTAL MODAL SURVEY OF THE PROBE MASS MOCK-UP
P. A. Manning and T. G. Woehrle Jul. 1992 42 p
(Contract W-7405-eng-48)
(DE93-008846; UCRL-ID-112191) Avail: CASI HC A03/MF A01

The Lawrence Livermore National Laboratory is engaged in a technology development project which includes designing a lightweight, autonomous, highly maneuverable space vehicle, commonly referred to as a probe. The current probe design includes a guidance and control system that requires complete information on the dynamic response of the probe during operation. A finite element model of the probe was constructed to provide analytical information on the dynamic response to specific operational inputs. In order to verify the assumptions made in the model, a mass mock-up of the probe was constructed at LLNL and an experimental modal survey was performed to determine the frequencies, damping values and deflection shapes for each natural mode of the mock-up. The experimental modal parameters were compared with the parameters obtained through modal analysis of the finite element model to provide a measure of the correlation between the model and the actual structure. This report describes the experimental modal testing and analysis of the mass mock-up and compares the experimental results with the finite element results. DOE

THE DYNAMICS AND CONTROL OF LARGE FLEXIBLE ASYMMETRIC SPACECRAFT Ph.D. Thesis
T. T. Humphries 1991 273 p
Avail: Univ. Microfilms Order No. BRDX97972

This thesis develops the equations of motion for a large flexible asymmetric Earth observation satellite and finds the characteristics of its motion under the influence of control forces. The mathematical model of the structure is produced using analytical methods. The equations of motion are formed using an expanded momentum technique which accounts for translational motion of the spacecraft hub and employs orthogonality relations between appendage and vehicle modes. The controllability and observability conditions of the full spacecraft motions using force and torque actuators are defined. A three axis reaction wheel control system is implemented for both slewing the spacecraft and controlling its resulting motions. From minor slew results it is shown that the lowest frequency elastic mode of the spacecraft is more important than higher frequency modes, when considering the effects of elastic motion on instrument pointing from the hub. Minor slews of the spacecraft configurations considered produce elastic deflections resulting in rotational attitude motions large enough to contravene pointing accuracy requirements of instruments aboard the spacecraft hub. Active vibration damping is required to reduce these hub motions to acceptable bounds in sufficiently small time. A comparison between hub mounted collocated and hub/appendage mounted non-collocated control systems verifies that provided the non-collocated system is stable, it can more effectively damp elastic modes whilst maintaining adequate damping of rigid modes. Analysis undertaken shows that the reaction wheel controller could be replaced by a thruster control system which decouples the modes of the spacecraft motion, enabling them to be individually damped.

NONLINEAR STABILITY ANALYSIS OF THE ATTITUDE MOTION OF SPIN-STABILIZED THRUSTING SPACECRAFT Ph.D. Thesis
Ja Young Kang 1992 154 p
Avail: Univ. Microfilms Order No. DA9237189

The attitude dynamics of a class of spin-stabilized, thrusting, upperstage spacecraft is examined. Certain spacecraft in the class has been observed to develop oscillations about their transverse axes which increase exponentially in magnitude by the time the solid propellant motor burns out. After burnout, the oscillations stabilize with approximately constant amplitudes. The basic model for examination consists of a rigid body, representing the spacecraft main body; and a point-mass spherical pendulum, representing a deposit of 'slag' formed as a by-product of the combustion of the solid propellant. Exact nonlinear equations of motion for the model are derived. Approximate nonlinear equations are obtained from these, by assuming that the mass of the slag deposit is much less than the total mass of the system. By applying certain additional restrictions, the coupled, approximate nonlinear equations are further simplified, and approximate near-resonant solutions are obtained by using the method of multiple scales. The results show that the slosh resonances caused by parametric and external type excitations due to the main body may occur. However, since the present system is a time-varying, nonstationary, nonlinear system, this study emphasizes the use of numerical methods based on using the exact nonlinear equations and real flight parameters of the WESTAR 4 spacecraft. Various slag disturbance models are used in the basic model. These include models of the effects of slag mass discharge, solidification, and viscosity. Attitude motions that result from numerical experiments performed using these slag models are very similar to observed motions of typical spin-stabilized upper stages. The best results are obtained by using the model in which a part of the slag mass is discharged through the nozzle near burnout time. Dissert. Abstr.

ESTIMATING SPARES REQUIREMENTS FOR SPACE STATION FREEDOM USING THE M-SPARE MODEL Final Report
Robert C. Kline and Craig C. Sherbrooke Aug. 1992 138 p
(Contract MDA903-90-C-0006)
(AD-A260878; LMI-NS101R1) Avail: CASI HC A07/MF A02

The Logistics Management Institute developed a methodology that estimates the optimal orbital replaceable unit (ORU) spares inventory for NASA's Space Station Freedom. NASA is using this methodology to select a spares inventory that will maximize station availability, i.e., the probability that no critical system is inoperative for lack of an ORU spare over the resupply cycle. It is based upon a marginal analysis approach. Spares are ranked in order of decreasing benefit per cost (the improvement provided to station availability per dollar) and added, in that order, to the inventory until a target resource expenditure or availability is reached. The methodology also develops optimal spares inventories constrained by the spares weight the shuttle can carry, the spares volume the station can store, or a combination of resources. To implement our methodology, we developed the Multiple Spares Prioritization and Availability to Resource Evaluation (M-SPARE) model that operates on a personal computer. M-SPARE presents the maximum availability for an entire range of resource expenditures. The model also converts annual spares requirements over any period of the station's life into funding estimates for the next 9 years. In this guide, we describe the M-SPARE methodology, operation, and analytical capabilities.

NONLINEAR DYNAMICS AND ATTITUDE CONTROL OF ARTICULATED FLEXIBLE SPACE STRUCTURES Ph.D. Thesis
Myung-Jin Baek 1992 177 p
Avail: Univ. Microfilms Order No. DA9305290

The present study is concerned with the development of a unified approach to the modeling and the design of an effective feedback linearizing and stabilizing nonlinear controller for multibody flexible and articulated systems. Modeling and control system design for such systems is of current interest. The principal objectives are to investigate the attitude regulation of rigid and/or flexible articulated multibody structures and to demonstrate how interacting nonlinear behaviors of flexible and articulated systems affect the stability and robustness properties of the controlled system. A systematic method for the formulation of the equations of motion for the nonlinear dynamics of flexible and articulated systems is employed based on a unified serial chain body algorithm, and this algorithm is integrated into Poincare's form of Lagrange's equations to formulate an innovative new approach to modeling of the system. The closed form solution of partial feedback linearization is derived using simple mathematical techniques and PFL compensation is applied as a general approach for the attitude decoupling and stabilization of the system having perfect knowledge of model uncertainties. The performance of a linear stabilizer, constructed on the same decoupling principle of the PFL stabilizer, is compared to that of

PFL stabilizer with respect to attitude decoupling and stabilization. In the presence of model uncertainties, parameter adaptive control method is combined with PFL to enhance stability and robustness properties. Throughout these analyses, it is shown that (1) the developed modeling procedure is an effective tool in constructing feedback linearizing control laws, (2) with the perfect knowledge of parametric uncertainties, PFL controller yields excellent performance with respect to attitude decoupling and stabilization, (3) the domain of attraction of the linear controller applied to nonlinear systems is critically small, and the boundary of stability is explained as a subcritical Hopf bifurcation, and (4) the equilibrium point of the closed-loop adaptive control system is asymptotically stable, but the domain of attraction of adaptive PFL is limited due to nonlinear effects between flexible and articulated bodies. EXTERNAL TANK AEROTHERMAL DESIGN CRITERIA VERIFICATION Final Report
Sarat C. Praharaj and Anthony J. Saladino 31 Jul. 1991 80 p
(Contract NAS8-38185)
(NASA-CR-192514; NAS 1.26:192514; RTR-227-01) Avail: CASI HC A05/MF A01

If a Space Shuttle Main Engine (SSME) fails during the initial 160 seconds of the Shuttle flight, a return-to-launch-site maneuver will be implemented. The period of concern for this task is the pitch-around maneuver when the vehicle is flying backward. The intent of this report is to identify and define the flowfield at the most critical locations from an environment perspective. The solution procedure used to predict the plume heating rates involves both computational analysis and engineering modeling. Author

Avail: CASI HC A02/MF A01

High voltage systems designed for use on the lunar and Martian surfaces or in orbit will interact with environmental components such as electrically charged dust, low pressure atmospheres, ionospheric plasmas and neutrals, and chemically reactive species. As the Space Exploration Initiative (SEI) advances from the realm of feasibility study to that of conceptual design, guidelines will be required to ensure that these effects are properly accounted for. A first step in providing such guidelines is the prioritization of interactions for each of the space or surface environments that will be encountered. For those issues that are identified as high priority, the state of environmental knowledge, emphasizing essential data, must be determined. This report describes possible means of obtaining such information, including ground tests, modeling and analysis, and flight experiments. The development of computational tools which will enable engineers to simulate and thereby quantify the interactions will be especially considered. Our analysis is drawn from various study and workshop activities undertaken within the last two years. Author

A study team at NASA's Lewis Research Center has been working on a definition study and conceptual design for a fluid physics and dynamics science facility that will be located in the Space Station Freedom's baseline U.S. Laboratory module. This modular, user-friendly facility, called the Fluid Physics/Dynamics Facility, will be available for use by industry, academic, and government research communities in the late 1990's. The Facility will support research experiments dealing with the study of fluid physics and dynamics phenomena. Because of the lack of gravity-induced convection, research into the mechanisms of fluids in the absence of gravity will help to provide a better understanding of the fundamentals of fluid processes. This document has been prepared as a final version of the handout for reviewers at the Fluid Physics/Dynamics Facility Assessment Workshop held at Lewis on January 24 and 25, 1990. It covers the background, current status, and future activities of the Lewis Project Study Team effort. It is a revised and updated version of a document entitled 'Status Report on the Conceptual Design for the Space Station Fluid Physics/Dynamics Facility', dated January 1990. Author

PLASMA CURRENT COLLECTION OF Z-93 THERMAL CONTROL PAINT AS MEASURED IN THE LEWIS RESEARCH CENTER'S PLASMA INTERACTION FACILITY
G. Barry Hillard Apr. 1993 14 p
(RTOP 506-41-41)
(NASA-TM-106132; E-7804; NAS 1.15:106132) Avail: CASI HC A03/MF A01

A sample of Z-93 thermal control paint was exposed to a simulated space environment in a plasma chamber. The sample was biased through a series of voltages ranging from -100 volts to +300 volts and electron and ion currents were measured. Currents were found to be in the micro-ampere range indicating that the material remains a reasonably good insulator under plasma conditions. As a second step, the sample was left in the chamber for six days and retested. Collected currents were reduced by from two to five times from the previous values indicating a substantial loss of conductivity. As a final test, the sample was removed, exposed to room conditions for two days, and returned to the chamber. Current measurements showed that the sample had partially recovered the lost conductivity. In addition to presenting these results, this report documents all of the experimental data as well as the statistical analyses performed. Author

Avail: CASI HC A05/MF A01

This report describes the second year of a scientific study of the interactions between the first flight of the Tethered Satellite System (TSS-1) and the ionosphere to increase understanding of the structure and current characteristics of high-voltage sheaths in the ionosphere. The investigations described here include an examination of electron collection and presheath structure by a positively biased, conducting sphere in the ionosphere moving at orbital velocity, including the effects of the earth's magnetic field and the current collection capabilities of the TSS-1 subsatellite considering the revised conductivity measurements. A BIPHASE SHIFT KEYING (BPSK), DIRECT SEQUENCE, SPREAD SPECTRUM MODEM FOR PETITE AMATEUR NAVY SATELLITE (PANSAT) M.S. Thesis
Thomas M. Fritz Dec. 1992 80 p
(AD-A261301) Avail: CASI HC A05/MF A01

The development of a biphase shift keying (BPSK), direct sequence, spread spectrum modem is conducted for the purpose of developing a prototype design to be implemented in Petite Amateur navy Satellite (PANSAT). The design discussion includes the hardware used in the functional realization of a working design. The design itself, encompasses selection of components, and demonstrates through circuit diagrams and waveforms produced that the preliminary operational characteristics of a spread spectrum BPSK modulation scheme for PANSAT have been achieved. Limited performance analysis is conducted through IF loop-back testing

and analyzes the demodulator output waveforms providing the proof of concept for the design. The development of the final version operating at the specified radio frequency (RF) is not conducted. DTIC

INVESTIGATION OF LIQUID SLOSHING IN SPIN-STABILIZED SATELLITES Final Report, 1 Jul. 1989 - 30 Nov. 1992
Joseph R. Baumgarten, Donald R. Flugrad, and Richard H. Pletcher 31 Jan. 1993 212 p
(Grant AF-AFOSR-0403-89)
(AD-A261671; ISU-ERI-AMES-93113; AFOSR-93-0077TR) Avail: CASI HC A10/MF A03

Several spin-stabilized communication satellites with liquid stores onboard have exhibited unstable nutational motion. Liquid sloshing is suspected as the cause of this undesirable behavior. During an initial three year grant period, a test rig was built and instrumented, a rigid body computer model was developed using a pendulum analogy to simulate the sloshing liquid, and computational fluid dynamics (CFD) methods were used to develop a primitive variable numerical algorithm to describe two and three dimensional liquid sloshing. During the current three year grant period, the test rig and rigid body computer model have been used to study the effect of various physical parameter values on the motion, and stability conditions have been determined. The structural mathematical model has been improved by introduction of finite element techniques to account for elastic deformation of the test rig, and an implicit-explicit numerical approach has been implemented to solve the coupled, nonlinear equations of motion. (Contract F49620-89-C-0084)
(AD-A261576; AFOSR-93-0080TR) Avail: CASI HC A13/MF A03

Research into methods for structural dynamical simulations control of large nonlinear notions of multi-body systems is summarized. A new Order N method is introduced which is shown to be a significant advancement for computing motions of nonlinear multi-body systems. A method is introduced for establishing globally stable maneuvers of flexible structures; both analytical and experimental results are presented. A new integration process is established which used the work/energy equation to stabilize the numerical integration of structural system differential equations. DTIC

This actuator and sensor handbook was developed during a cooperative project between the NASA-Marshall Space Flight Center, the SDI-Directed Energy Program, and Lawrence Livermore National Laboratory (LLNL). The common purpose of the joint effort was to develop precision actuators and sensors for the NASA initiated SpacE Laser ENE-rgy Program (SELENE). The purpose of the SELENE Program is to develop a highly cost effective segmented adaptive optics system for beaming laser power directly to spacecraft in earth orbit. DOE

ASPECTS OF THE DESIGN OF A SATELLITE BORNE INFRA-RED RADIOMETER Ph.D. Thesis
Stephen T. R. Werrett 1991 255 p
Avail: Univ. Microfilms Order No. BRD-97323

In an attempt to address some of the current concerns about changes in the composition of the upper atmosphere, the Upper Atmosphere Research Satellite (UARS) program was undertaken by NASA. The program is outlined and the satellite itself described. The Improved Stratospheric And Mesospheric Sounder (ISAMS) measures, from the UARS, infra-red radiation emitted by the atmosphere with the intention that temperature and the concentrations of important trace gases may be deduced. In order to improve the quality of the measurements it is necessary that the infra-red detectors and some optical components be cooled. At the time when the instrument development started no method of long term cooling to the required temperature of 80 K was available. Stirling cycle coolers were developed and the instrument designed to use them in conjunction with a 200 K radiative cooler. A cooling and support system for the detectors was developed. Low conductivity, all metal, supports are combined with a co-axial thermal conductor arrangement. Measurements were carried out to determine the performance of the detector support and cooling system. Excellent agreement between design calculations and measured performance was demonstrated. Measurements of the behavior of the gas in the Stirling cycle coolers was compared with predictions from mathematical models and this led to improved and repeatable performance. An electronic servo control system was developed for the cooler mechanisms. Performance of the coolers was measured in a thermal vacuum chamber in order to plan for the proper operation of them in the instrument and to be able to predict their performance. Tests were carried out in order to establish confidence in their suitability for a spacecraft installation. The ISAMS instrument requires an on board computer for its interaction with the spacecraft and ultimately its ground controllers. In addition, this system must support the loading and running of measurement sequence control programs. The system is microprocessor based and features data bus based control and data collection. Software for the microprocessor performs the basic data collection and command response tasks and allows for the running of the sequence control programs. A combination of a compiler in a ground computer and an interpreter in the microprocessor permit programs to be written in a high level language designed for this purpose.

As the size and sophistication of spacecraft have increased, anomalies in operational performance caused by the interaction of the energetic-particle population and the spacecraft have likewise increased. The Compact Environmental Anomaly Sensor (CEASE) is being developed as a small, low-power device to monitor space weather and provide autonomous warning of conditions that could cause operational anomalies. Based on the sensor-design and trade-off studies for CEASE, a dosimeter set consisting of solid-state detectors behind aluminum absorbers (of several thicknesses) has been chosen. The outputs of the detectors are fed into algorithms that warn of certain anomalies: (1) surface dielectric charging, (2) deep dielectric charging, (3) total radiation dose behind 0.035 g/cm to the 2nd power, (4) total dose behind 0.41 g/cm to the 2nd power, and (5) single event upsets. From seven quantities derived by algorithm processing, eight warning levels (1, 3, 100...3000 x base) are obtained for each of the five anomalies. Level flags can then be selected for a particular application. For such a CEASE instrument, we estimate a volume of 64 in.to the 3rd power (4-inch cube), a weight of 2 pounds, and power dissipation of 2 watts. DTIC

NASA LeRC was selected to lead nuclear propulsion technology development for NASA. Also participating in the project are NASA MSFC and JPL. The U.S. Department of Energy will develop nuclear technology and will conduct nuclear component, subsystem, and system testing at appropriate DOE test facilities. NASA program management is the responsibility of NASA/RP. The project includes both nuclear electric propulsion (NEP) and nuclear thermal propulsion (NTP) technology development. This report summarizes the efforts of an interagency panel that evaluated NTP technology in 1991. Other panels were also at work in 1991 on other aspects of nuclear propulsion, and the six panels worked closely together. The charters for the other panels and some of their results are also discussed. Important collaborative efforts with other panels are highlighted. The interagency (NASA/DOE/DOD) NTP Technology Panel worked in 1991 to evaluate nuclear thermal propulsion concepts on a consistent basis. Additionally, the panel worked to continue technology development project planning for a joint project in nuclear propulsion for the Space Exploration Initiative (SEI). Five meetings of the panel were held in 1991 to continue the planning for technology development of nuclear thermal propulsion systems. The state-of-the-art of the NTP technologies was reviewed in some detail. The major technologies identified were as follows: fuels, coatings, and other reactor technologies; materials;

instrumentation, controls, health monitoring and management, and associated technologies; nozzles; and feed system technology, including turbopump assemblies. Author (revised)

SUMMARY AND RECOMMENDATIONS ON NUCLEAR ELECTRIC PROPULSION TECHNOLOGY FOR THE SPACE EXPLORATION INITIATIVE

Michael P. Doherty and Robert S. Holcomb (Oak Ridge National Lab., TN.) Apr. 1993 120 p

(RTOP 593-72-00)

(NASA-TM-105707; E-7783; NAS 1.15:105707) Avail: CASI HC A06/MF A02

A project in Nuclear Electric Propulsion (NEP) technology is being established to develop the NEP technologies needed for advanced propulsion systems. A paced approach has been suggested which calls for progressive development of NEP component and subsystem level technologies. This approach will lead to major facility testing to achieve TRL-5 for megawatt NEP for SEI mission applications. This approach is designed to validate NEP power and propulsion technologies from kilowatt class to megawatt class ratings. Such a paced approach would have the benefit of achieving the development, testing, and flight of NEP systems in an evolutionary manner. This approach may also have the additional benefit of synergistic application with SEI extraterrestrial surface nuclear power applications. Author (revised)

SPACE EXPLORATION INITIATIVE CANDIDATE NUCLEAR PROPULSION TEST FACILITIES

Darrell Baldwin (Sverdrup Technology, Inc., Brook Park, OH.) and John S. Clark Apr. 1993 259 p

(RTOP 593-71-00)

(NASA-TM-105710; E-7759; NAS 1.15:105710) Avail: CASI HC A12/MF A03

One-page descriptions for approximately 200 existing government, university, and industry facilities which may be available in the future to support SEI nuclear propulsion technology development and test program requirements are provided. To facilitate use of the information, the candidate facilities are listed both by location (Index L) and by Facility Type (Index FT). The included one-page descriptions provide a brief narrative description of facility capability, suggest potential uses for each facility, and designate a point of contact for additional information that may be needed in the future. The Nuclear Propulsion Office at NASA Lewis presently plans to maintain, expand, and update this information periodically for use by NASA, DOE, and DOD personnel involved in planning various phases of the SEI Nuclear Propulsion Project. EXPERIMENTATION IN THE LOW-DENSITY PLUME OF A SIMULATED ELECTROTHERMAL THRUSTER FOR COMPUTER CODE VALIDATION Final Report

Dana L. Meissner (Toledo Univ., OH.) Apr. 1993 86 p

(Grant NAG3-577; RTOP 506-42-31)

(NASA-CR-191112; E-7728; NAS 1.26:191112) Avail: CASI HC A05/MF A01

Pressures and flow angles are measured in the plume of a 20 deg half-angle, conical nozzle in vacuum with Pitot tubes and conical probes. The area of measurement in the plume ranges from the nozzle exit plane to 480 mm axially downstream and from the plume centerline to 60 mm radially. The nozzle has an exit-to-throat area ratio of 100:1 and a throat diameter of 3.2 mm. The nozzle flow exhausts to a vacuum of order 10(exp -2) Pa to simulate a resistojet (an electrothermal rocket of less than 1 N of thrust) operating in space. Experimental data are given for flows of nitrogen at 55 and 68 mg/s, stagnation temperatures between 695 and 921 K, and stagnation pressures ranging from 5600 to 7100 Pa. Data are also given for argon at a rate of 68 mg/s, a stagnation temperature of 648 K, and stagnation pressures of 4500, 4750, and 4770 Pa. Measurements in the nitrogen plume are compared with computational results from a direct-simulation Monte Carlo method. Author (revised)

[VIEWGRAPH DESCRIPTION OF PENN STATE'S PROPULSION ENGINEERING RESEARCH CENTER: ACTIVITY HIGHLIGHTS AND FUTURE PLANS] Annual Report

Charles L. Merkle Jan. 1991 75 p Presented at the Annual Review Meeting of the University Space Engineering Research Program, Washington, DC, 22-23 Jan. 1991

(Grant NAGw-1356)

(NASA-CR-192317; NAS 1.26:192317) Avail: CASI HC A04/MF A01

Viewgraphs are presented that describe the progress and status of Penn State's Propulsion Engineering Research Center. The Center was established in Jul. 1988 by a grant from NASA's University Space Engineering Research Centers Program. After two and one-half years of operation, some 16 faculty are participating, and the Center is supporting 39 graduate students plus 18 undergraduates. In reviewing the Center's status, long-term plans and goals are reviewed and then the present status of the Center and the highlights and accomplishments of the past year are summarized. An overview of plans for the upcoming year are presented. Author (revised)

A NEURAL NETWORK-BASED ESTIMATOR FOR THE MIXTURE RATIO OF THE SPACE SHUTTLE MAIN ENGINE

T. H. Guo and J. Musgrave Nov. 1992 12 p Presented at the Fourth Annual Health Monitoring Conference for Space Propulsion Systems, Cincinnati, OH, 17-18 Nov. 1992; sponsored by Univ. of Cincinnati

(RTOP 582-01-11)

(NASA-TM-106070; E-7675; NAS 1.15:106070) Avail: CASI HC A03/MF A01

In order to properly utilize the available fuel and oxidizer of a liquid propellant rocket engine, the mixture ratio is closed loop controlled during main stage (65 percent - 109 percent power) operation. However, because of the lack of flight-capable instrumentation for measuring mixture ratio, the value of mixture ratio in the control loop is estimated using available sensor measurements such as the combustion chamber pressure and the volumetric flow, and the temperature and pressure at the exit duct on the low pressure fuel pump. This estimation scheme has two limitations. First, the estimation formula is based on an empirical curve fitting which is accurate only within a narrow operating range. Second, the mixture ratio estimate relies on a few sensor measurements and loss of any of these measurements will make the estimate invalid. In this paper, we propose a neural network-based estimator for the mixture ratio of the Space Shuttle Main Engine. The estimator is an extension of a previously developed neural network based sensor failure detection and recovery algorithm (sensor validation). This neural network uses an auto associative structure which utilizes the redundant information of dissimilar sensors to detect inconsistent measurements. Two approaches have been identified for synthesizing mixture ratio from measurement data using a neural network. The first approach uses an auto associative neural network for sensor validation which is modified to include the mixture ratio as an additional output. The second uses a new network for the mixture ratio estimation in addition to the sensor validation network. Although mixture ratio is not directly measured in flight, it is generally available in simulation and in test bed firing data from facility measurements of fuel and oxidizer volumetric flows. The pros and cons of these two approaches will be discussed in terms of robustness to sensor failures and accuracy of the estimate during typical transients using simulation data. Author (revised)

SPACE NUCLEAR THERMAL PROPULSION TEST FACILITIES SUBPANEL Final Report

George C. Allen (Sandia National Labs., Albuquerque, NM.), John W. Warren (Department of Energy, Washington, DC.), John Martinell (Idaho National Engineering Lab., Idaho Falls.), John S. Clark, and David Perkins (Phillips Lab., Edwards AFB, CA.) Apr. 1993 178 p

(RTOP 593-71-00)

(NASA-TM-105708; E-7781; NAS 1.15:105708) Avail: CASI HC A09/MF A02

On 20 Jul. 1989, in commemoration of the 20th anniversary of the

Apollo 11 lunar landing, President George Bush proclaimed his vision for manned space exploration. He stated, 'First for the coming decade, for the 1990's, Space Station Freedom, the next critical step in our space endeavors. And next, for the new century, back to the Moon. Back to the future. And this time, back to stay. And then, a journey into tomorrow, a journey to another planet, a manned mission to Mars.' On 2 Nov. 1989, the President approved a national space policy reaffirming the long range goal of the civil space program: to 'expand human presence and activity beyond Earth orbit into the solar system.' And on 11 May 1990, he specified the goal of landing Astronauts on Mars by 2019, the 50th anniversary of man's first steps on the Moon. To safely and ever permanently venture beyond near Earth environment as charged by the President, mankind must bring to bear extensive new technologies. These include heavy lift launch capability from Earth to low-Earth orbit, automated space rendezvous and docking of large masses, zero gravity countermeasures, and closed loop life support systems. One technology enhancing, and perhaps enabling, the piloted Mars missions is nuclear propulsion, with great benefits over chemical propulsion. Asserting the potential benefits of nuclear propulsion, NASA has sponsored workshops in Nuclear Electric Propulsion and Nuclear Thermal Propulsion and has initiated a tri-agency planning process to ensure that appropriate resources are engaged to meet this exciting technical challenge. At the core of this planning process, NASA, DOE, and DOD established six Nuclear Propulsion Technical Panels in 1991 to provide groundwork for a possible tri-agency Nuclear Propulsion Program and to address the President's vision by advocating an aggressive program in nuclear propulsion. To this end the Nuclear Electric Propulsion Technology Panel has focused it energies; this final report summarizes its endeavor and conclusions. Author (revised)

LASER BEAMED POWER: SATELLITE DEMONSTRATION APPLICATIONS Final Report

Geoffrey A. Landis and Larry H. Westerlund (Satellite Communications Consultants, Rockville, MD.) Aug. 1992 19 p Presented at the 43rd Congress of the International Astronautical Federation, Washington, DC, 28 Aug. - 3 Sep. 1992; sponsored by International Astronautical Federation Previously announced in IAA as A92-57056

(Contract NAS3-25266; RTOP 506-41-11)

(NASA-CR-190793; E-7629; NAS 1.26:190793; IAF-92-0600) Avail: CASI HC A03/MF A01

It is possible to use a ground-based laser to beam light to the solar arrays of orbiting satellites, to a level sufficient to provide all or some of the operating power required. Near-term applications of this technology for providing supplemental power to existing satellites are discussed. Two missions with significant commercial pay-off are supplementing solar power for radiation-degraded arrays and providing satellite power during eclipse for satellites with failed batteries. The theory and procedures for determining the characteristics of pressure oscillations in rocket engines with prescribed burning rate oscillations are presented. Pressure and velocity oscillations calculated using this procedure are presented for the Space Shuttle Main Engine (SSME) to show the influence of baffles and absorbers on the burning rate oscillations required to achieve neutral stability. Results of calculations to determine local combustion responses using detailed physical models for injection, atomization, and vaporization with gas phase oscillations in baffled and unbaffled SSME combustors are presented. The contributions of the various physical phenomena occurring in a combustor to oscillations in combustion response were determined. Author

THE DESIGN OF A PROPULSION SYSTEM USING VENT GAS FROM A LIQUID HELIUM CRYOGENIC SYSTEM Ph.D. Thesis

Peter J. Wiktor 1992 244 p

Avail: Univ. Microfilms Order No. DA9302338

Two spacecraft, Gravity Probe B (GP-B) and the Satellite Test of the Equivalence Principle (STEP), incorporating on-board liquid helium cryogenic systems are scheduled to fly around the turn of the century. Effective propulsion systems can be implemented for these spacecraft by directing the helium gas which boils off from the cryogenic systems in specific directions through a set of thrusters. Due to extensive development and testing work at Stanford and elsewhere, the ultra low flow rate helium thrusters for such a propulsion system are now considered proven technology. This thesis is concerned with implementing these thrusters into an effective overall propulsion system. Our primary concern is maximizing the forcing capability or control authority of the propulsion system. A worst case analysis of the thruster system is performed. Various techniques are derived to calculate the worst case output or minimum control authority of the thruster system. The techniques are general and apply to any parallel configuration of actuators. They are used in this thesis to design a propulsion system for GP-B which maximizes the minimum control authority and to study redundancy of the GP-B thruster system under a worst case thruster failure. A general thruster controller is derived for a liquid helium propulsion system which can generate desired output forces and at the same time vent the required helium gas needed to cool the cryogenic system. We show how the helium gas vent rate can be controlled to maintain a stable liquid helium supply temperature and pressure. An on-orbit thruster calibration scheme is developed to make sure the correct output force is generated. Using a nonlinear simulation of the spacecraft dynamics, the calibration scheme is shown to calibrate the 108 parameters needed to describe the outputs of a set of 18 thrusters to better than 1 percent accuracy. Finally an on-orbit mass trim control system is derived to reduce the centrifugal force and moment disturbances on the propulsion system due to mass property offsets. Dissert. Abstr.

ANODE POWER DEPOSITION IN COAXIAL MPD THRUSTERS Ph.D. Thesis

Alec Damian Gallimore 1992 225 p

Avail: Univ. Microfilms Order No. DA9302051

An array of diagnostic techniques was used to study anode phenomena in quasi-steady self-field MPD thrusters operated at power levels between 150 kW and 7 MW with argon and helium propellants. Spatially resolved anode heat flux measurements were made by embedding thermocouples to the inner surface of a hollowed section of the anode. These measurements indicate that at a thruster power level of 1 MW over 40 percent of the input power was deposited into the anode while at 7 MW this fraction decreased to less than 20 percent. The peak measured anode heat flux was approximately 10 kW/sq cm. Electron temperature and anode current densities were measured via Langmuir and magnetic probes, respectively, which with heat flux measurements permitted an estimate of the anode fall to be made. In addition, floating probes, which were used to measure the anode fall, served as a second means of estimating the anode heat flux. Comparison of anode fall data acquired through either method showed excellent agreement. Anode falls varied between 4 and 50 V for both argon and helium propellants. Furthermore, the anode fall was found to correlate well with electron Hall parameters calculated from triple Langmuir and magnetic probe data collected near the anode. Two possible explanations for this result are proposed: the establishment of large electric fields at the anode to maintain current conduction across the strong magnetic fields; anomalous resistivity resulting from the onset of microturbulence in the plasma. To investigate the latter hypothesis, electric field, magnetic field, and current density profiles measured in the vicinity of the anode were incorporated into Ohm's law to estimate electrical conductivity. Results of this analysis show a substantial deviation of the measured conductivity from that calculated with classical formulae. These results imply that anomalous effects are present in the plasma near the anode. In an attempt at reducing the anode fall by decreasing the local electron Hall parameter, a proof-of-concept test was conducted in which thirty six permanent magnets were embedded within an anode to counteract the ambient magnetic field.

The results of this experiment were promising with a reduction of the anode fall of up to 15 V (37 percent) with argon and 20 V (50 percent) with helium. Dissert. Abstr.

AN IN-DEPTH PROBABILISTIC STUDY OF EXTERNAL TANK ATTACH RING

Frank Pizzano and C. S. Putcha (California State Coll., Fullerton.) Apr. 1993 65 p

(NASA-TM-108403; NAS 1.15:108403) Avail: CASI HC A04/MF A01

This report deals with conducting a probabilistic study of the external tank attach ring (ETA) used as an interface between the external tank attach struts and the solid rocket booster. The ideas were to use probabilistic distributions for material, geometric, and load properties; to calculate probabilistic margins of safety; and then to compare results against the deterministic factors of safety that were used in the actual design process. The report describes how this was done and discusses some of the road blocks and data problems that were encountered during the study and provides some conclusions. A further refinement of this study is being considered for future work which would make more direct use of finite element analysis data coupled with Monte Carlo simulation. The basic conclusion herein indicates that the probabilistic margins of safety for the cases analyzed (by use of existing data) appear to support deterministic results and actually indicate higher reliabilities. PARTICLE BEHAVIOR IN SOLID PROPELLANT ROCKET MOTORS AND PLUMES M.S. Thesis

John D. McCrorie, II Dec. 1992 56 p

(AD-A260900) Avail: CASI HC A04/MF A01

The particle size distribution inside the combustion chamber and the changes that occurred across the exhaust nozzle were measured in a subscale solid propellant rocket motor with a 2 percent aluminized end-burning propellant grain and a highly underexpanded nozzle. A combination of diagnostic techniques were used. Size distributions in the exhaust plume were determined by a Single Particle Counter, a Malvern 2600 ensemble particle sizer, and by Scanning Electron Microscope (SEM) examinations of particles collected on a timed exposure impact probe. Size distributions inside the combustion chamber were determined by Malvern 2600 measurements through windows at the nozzle entrance, SEM examinations of particles collected from the nozzle entrance wall, and exhaust plume measurements of a helium quenched motor. It was determined that agglomeration processes dominated in the flow from the center of the combustion chamber up to the nozzle entrance. Particle breakup processes dominated particle behavior from the nozzle entrance, through the nozzle, and into the exhaust. DTIC

VISUALIZATION OF A MACH 2 REACTING FLOW USING PLANAR LASER-INDUCED FLUORESCENCE (PLIF) **c09**

R. Jeffrey Balla *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 1-7 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Planar laser-induced fluorescence (PLIF) has been used to study the mixing and combustion processes in a coaxial hydrogen/vitiated air turbulent reacting flow. Objectives of this study include providing qualitative information about: (1) the location of flow constituents; (2) the size, location, and orientation of instantaneous and average flow structures; and (3) the unsteadiness of the flow field. The flow facility consists of an inner fuel jet (I.D.= 2.36 mm) which injects hydrogen (Mach = 1 at 550K) and an outer jet (I.D. = 17.8 mm) which injects vitiated air (Mach = 2 at 1250K). This coaxial arrangement generates a turbulent diffusion flame. The flow field is visualized using a tunable excimer laser operating with XeCl and having a pulse length of 20 nanoseconds. The laser beam is formed into a sheet approximately 12.7 cm high and 0.3 mm thick. Laser-induced fluorescence (LIF) is generated by tuning the laser to 32,441.85 cm(exp -1) which excites the Q1(3) transition in the (0-0) band of the A 2Sigma(+) - X 2Pai system of OH. The fluorescence from all emission lines of the (0-0) band is imaged on an intensified CCD array detector, digitized, and stored for later analysis. Instantaneous images provide insight into the flow field which the average data cannot. Preliminary results indicate the presence of both large and small scale flow features in the instantaneous laser snapshots generated from the OH PLIF. In approximately 5-10 percent of the instantaneous images, the PLIF signal is minimal over a significant fraction of the flow field. Finally, it is observed that OH is present in the vitiated air and is transported over a significant fraction of the flow field. Author

STUDIES IN AIR/AIR SUPERSONIC MIXING LAYERS **c02**

D. J. Risha and B. Sekar *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 9-18 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Results for the numerical simulation of a two-dimensional, supersonic, air-to-air shear layer with convective Mach numbers of 0.1 and 0.46 are presented. A two-dimensional Navier-Stokes code (SPARK2D), using a 4th order, cross MacCormack, time-accurate integration scheme is used to numerically solve the flow equations. Two versions of the code are used: (1) direct numerical simulations (DNS), and a two-equation k-epsilon turbulence model. Comparison of the DNS solutions with experimental results shows similar trends in the shear layer growth rate and the statistical parameters (stream wise turbulent intensity, transverse turbulent intensity, kinematic Reynolds stress) but at reduced magnitudes. Comparison of the k-epsilon simulated solutions with experimental results also showed similar trends in the shear layer growth rate and statistical parameters and are moderately comparable in magnitudes. However, all simulated results degrade with increasing convective Mach number. The validity and requirements of the DNS towards simulating a realistic laboratory test is argued in light of the available lessons learned and weighed against the engineering approaches. Author

WORKSHOP REPORT: A VALIDATION STUDY OF NAVIER-STOKES CODES FOR TRANSVERSE INJECTION INTO A MACH 2 FLOW **c34**

Dean R. Eklund (Analytical Services and Materials, Inc., Hampton, VA.), G. Burton Northam, J. C. McDaniel (Virginia Univ., Charlottesville.), and Cliff Smith (CFD Research Corp., Huntsville, AL.) *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 19-34 Previously announced as A93-21330 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A CFD (Computational Fluid Dynamics) competition was held at the Third Scramjet Combustor Modeling Workshop to assess the current state-of-the-art in CFD codes for the analysis of scram jet combustors. Solutions from six three-dimensional Navier-Stokes codes were compared for the case of staged injection of air behind a step into a Mach 2 flow. This case was investigated experimentally at the University of Virginia and

extensive in-stream data was obtained. Code-to-code comparisons have been made with regard to both accuracy and efficiency. The turbulence models employed in the solutions are believed to be a major source of discrepancy between the six solutions. Author

THE EFFECT OF ENTRANCE RADIUS AND FILM INJECTION ON WALL HEATING IN SCRAMJET NOZZLES
N. R. Baker (Lockheed Engineering and Sciences Co., Hampton, VA.), G. B. Northam, D. P. Capriotti (Analytical Services and Materials, Inc., Hampton, VA.), and S. D. Stouffer (Virginia Polytechnic Inst. and State Univ., Blacksburg.) *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 35-46 Previously announced as A93-22505 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

An experimental study has been performed with a scramjet combustor and nozzle model to determine the effect of nozzle radii on relaminarization, and the effectiveness of film injection in reducing wall heat flux. The nozzle model was installed downstream of a swept-ramp scram jet combustor model, operated at Mach 2.7 with vitiated air, simulating Mach 6-7 flight enthalpies. Results from tests conducted with three nozzle radii, varying in curvature from a sharp Prandtl-Meyer expansion to a radius of two scramjet combustor exit heights, showed little or no effect on the downstream wall heat flux, which is not in agreement with both subsonic and supersonic relaminarization correlations in the available literature. In contrast, film injection upstream of all three radii produced reductions of 70 percent the entire nozzle model heating rate, for the nominal film-to-free stream pressure matched condition. Results from film injection, with and without pressure gradient, but without wall curvature, show that the gradients appear to stabilize the film, with the resulting reductions in wall heat transfer rates apparent far downstream of the point of injection. SOLID FUEL SUPERSONIC COMBUSTION **c25**
W. J. Angus, M. A. Witt, D. Laredo, and D. W. Netzer *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 47-57 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A solid fuel scramjet which utilized a combustor made of Plexiglas has been successfully demonstrated. Hot air entered the Plexiglas combustor with a Mach number of 1.5. A small amount of hydrogen gas was injected into a mixed supersonic-subsonic flame stabilization zone at the head-end of the combustor to help sustain combustion. The combustor consisted of a short, constant area section followed by a diverging section. Combustor exit Mach numbers were typically 1.1-1.4 and combustion efficiencies as high as 87 percent have been attained with equivalence ratios between 0.49-0.65. Nozzle exit temperature rake measurements indicated that the rough surface generated in the near thermally choked constant diameter region generated enough mixing to provide high centerline temperatures. However, to date the heat addition and wall friction induced losses have resulted in 50-70 percent losses in stagnation pressure across the combustor. Author

GASP 1.3 RESULTS FOR THE TRANSVERSE HYDROGEN REACTING JET **c25**
Balu Sekar *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 59-76 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The three-dimensional Navier-Stokes Code, GASP 1.3, was used to predict the air-to-air mixing for a twin jet configuration in a step-type of combustor with transverse injection, air-to-air mixing for an axial injection from a swept-ramp base, and air-H2 mixing and reaction for flow in a step-type of combustor. Turbulence was modeled with an algebraic eddy viscosity model. Chemically reacting flow was modeled with seven species with a seven-reaction mechanism. For the air-to-air mixing, effect of Turbulent Schmidt Number on the predicted mixing revealed that predictions with a Turbulent Schmidt Number of 0.5 compare well with the data. Numerical study of the axial injection from the swept-ramp base also supports this fact. The air-H2 mixing and reacting study included two expansion angles of two degrees and eight degrees at a total temperature of 1500K. The calculations revealed that mixing efficiency is not greatly affected by the increase in the expansion angle, but combustion efficiencies seem to depend on the expansion angle and decreased with the increased expansion angle. For the same mass flow rate of the fuel (for the same phi) and for the same fuel jet area, jet shapes with increased blockage like a square, and a circle in the crosswise plane, appear to yield higher combustion efficiencies, higher temperature and pressure at the end of the studied combustor configuration. TURBULENCE INTERACTING WITH CHEMICAL KINETICS IN AIRBREATHING COMBUSTION OF DUCTED ROCKETS
T. J. Chung and W. S. Yoon *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 77-90 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Physical interactions between turbulence and shock waves are very complex phenomena. If these interactions take place in chemically reacting flows the degree of complexity increases dramatically. Examples of applications may be cited in the area of supersonic combustion, in which the controlled generation of turbulence and/or large scale vortices in the mixing and flame holding zones is crucial for efficient combustion. Equally important, shock waves interacting with turbulence and chemical reactions affect the combustor flowfield resulting in enhanced relaxation and chemical reaction rates. Chemical reactions in turn contribute to dispersion of shock waves and reduction of turbulent kinetic energies. Computational schemes to address these physical phenomena must be capable of resolving various length and time scales. These scales are widely disparate and the most optimum approach is found in explicit/ implicit adjustable schemes for the Navier-Stokes solver. This is accomplished by means of the generalized Taylor-Galerkin (GTG) finite element formulations. Adaptive meshes are used in order to assure efficiency and accuracy of solutions. Various benchmark problems are presented for illustration of the theory and applications. Geometries of ducted rockets, supersonic diffusers, flame holders, and hypersonic inlets are included. Merits of proposed schemes are demonstrated through these example problems. Author

PARTICLE SIZE AS A FACTOR IN AGGLOMERATION IN SLURRY FUELS **c28**
P. Roy Choudhury *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 91-99 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A series of experiments with JP-10 slurries, prepared with inert particles ranging in size from 0.3 to 22 micron, has been performed to study the influence of particle size on particle agglomeration in a slurry fuel. Inert SiC and Al2O3 particles were chosen to avoid the complexities associated with reacting solids. Similarly, slurries were prepared without any chemical additives which could decompose. The choice of non-stabilized slurry with inert particles was made in order not to cloud the issue of particle agglomeration due to secondary reactions. Scanning Electron Microscopic (SEM) studies of the residues from burning and also evaporating droplets suggest that instead of using very small particles (1 micron or smaller), intermediate size particles (approximately 3 microns) should be used in preparing the slurries. Intermediate size particles are affected neither by any interacting forces nor by chemical cementation caused by fuel decomposition at the particle surface. Therefore, the intermediate size particles are expected to minimize particle agglomeration. Author

A SUMMARY OF THE JANNAF WORKSHOP ON LIQUID ROCKET ATOMIZATION
D. J. Hautman *In* JHU, 29th JANNAF Combustion Subcommittee Meeting,

Volume 2 Oct. 1992 p 101-107 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A JANNAF sponsored workshop, entitled 'Assessment of the Liquid Rocket Atomization Research Activities' was held after the 28th JANNAF Combustion Meeting in San Antonio, Texas. The objective of the workshop was to review current programs in the area of liquid rocket atomization and to identify research areas not being investigated by these programs. As a result of presentations during the JANNAF Combustion Meeting and during the workshop, current programs were reviewed and discussed. Recommendations for additional programs were then made with a level of importance being assigned to each program. The workshop also established a committee to summarize in a single document typical ranges of actual liquid rocket injector operating parameters, non-dimensional parameters, and liquid propellant/simulation properties. Finally, the workshop recommended that a committee be formed to investigate what procedures should be instituted for droplet size/velocity measurement technique calibration. Author

MEASUREMENT OF DROPLET VAPORIZATION RATE ENHANCEMENT CAUSED BY ACOUSTIC DISTURBANCES
T. J. Anderson and M. Winter *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 109-117 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Advanced laser diagnostics are being applied to quantify droplet vaporization enhancement in the presence of acoustic fields which can lead to instability in liquid-fueled rockets. While models have been developed to describe the interactions between subcritical droplet vaporization and acoustic fields in the surrounding gases, they have not been verified experimentally. In the super critical environment of a rocket engine combustor, little is understood about how the injected fluid is distributed. Experiments in these areas have been limited because of the lack of diagnostic techniques capable of providing quantitative results. Recently, however, extremely accurate vaporization rate measurements have been performed on droplets in a subcritical environment using morphology-dependent resonances (MDR's) in which fluorescence from an individual droplet provides information about its diameter. Initial measurements on methanol droplets behind a pressure pulse with a pressure ratio of 1.2 indicated that the evaporation rate in the first few microsec after wave passage was extremely high. Subsequent measurements have been made to validate these results using MDR's acquired from similarly-sized droplets using a pulse with a 1.1 pressure ratio. A baseline measurement was also made using a non evaporative fluid under similar Weber and Reynolds number conditions. The MDR technique employed for these measurements is explained and the facilities are described. The evaporation measurement results are shown and the rates observed from different droplet materials and different wave strengths are compared.

DEVELOPMENT OF A SECOND GENERATION SPRAY COMBUSTION CODE **c25**
Pak-Yan Liang *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 119-129 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Development has been initiated for a new family of multiphase, multispecies rocket spray combustion codes aimed at improving turnaround time over the first generation codes by up to one order of magnitude. Early versions integrate a proven, robust numerical platform with existing physical submodels, but with provision for continuous assimilation of future advanced performance enhancing features carefully designed into the code framework. The basic numerical extensions necessarily are described. Trial runs with one partially completed code version seem to indicate that a five times speed up is readily achievable at least for steady state flow.

EULERIAN-EULERIAN TREATMENT OF TURBULENT DENSE SPRAY COMBUSTION IN A BIPROPELLANT LIQUID ROCKET ENGINE
H. K. Navaz (Physical Research, Inc., Torrance, CA.), A. L. Dang (Physical Research, Inc., Torrance, CA.), and K. W. Gross *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 131-141 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The Liquid Thrust Chamber Performance (LTCP) code is used to analyze the two-phase flow, evaporation and combustion processes in the F-1 engine. This engine uses LOX/RP-I as propellants. Multi-phase flow equations are solved in an Eulerian-Eulerian (E2) framework, and multi-step finite rate chemistry is used for combustion analysis. The discretization scheme is fully implicit and is based on the Total Variation Diminishing (TVD) scheme, which is accurate, robust, very efficient and capable of handling steep gradients and stiff chemistry. Results obtained from the LTCP program have been compared with available performance data.

A NEW APPROACH TO COOLED COMBUSTION CHAMBERS: THE 40K FORMED PLATELET CHAMBER
David E. Janke and William A. Hayes *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 143-148 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Regeneratively cooled combustion chambers constructed with formed platelet liners have many benefits over chambers with conventionally machined liners. The formed platelet liner offers increased heat transfer efficiency, which can increase cycle life and enhance wall compatibility. A combustion chamber of the 40,000 lb thrust size has been fabricated and tested with a formed platelet liner to demonstrate this superior heat transfer capability. Chamber and liner design and fabrication process are presented in this paper. Author

HYBRID ROCKET FUEL COMBUSTION STUDY **c25**
L. D. Strand and N. S. Cohen (Cohen, Norman S. Professional Services, Inc., Redlands, CA.) *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 149-154 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The objectives of this hybrid rocket study are to extend our understanding of the nature of the boundary layer combustion process and the critical engineering parameters that define this process. Tests were carried out with a hybrid slab window motor, using several diagnostic techniques, over a range of motor pressure and oxidizer mass flux using both single and double (opposed) fuel slabs. The results, detailed in the paper, basically confirmed turbulent boundary layer heat and mass transfer as the rate limiting process for hybrid fuel decomposition and combustion. Author

THERMAL RADIATION IN NON-METALIZED SOLID ROCKET MOTORS: EFFECT ON BURNING RATE AND TEMPERATURE SENSITIVITY
M. Q. Brewster and S. F. Son *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 155-163 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Thermal radiation from combustion gases in non-metalized solid rocket motors is examined using band model calculations. These calculations show that even pure molecular gas radiation (no particles) can reach near black body levels for realistic motor conditions. The effects of thermal radiation on burning rate and temperature sensitivity are also examined. It is shown that differences in burning rate and temperature sensitivity between motors and propellant strands which in the past have primarily been attributed to erosive burning, could in some instances be due to thermal gas radiation.

The implications of gas radiation on combustion stability are also discussed. It is shown that radiative feedback may have either a stabilizing or de-stabilizing effect, according to the temperature dependence of the temperature sensitivity sigma(sub p)(T(sub 0)). Author

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

This paper reviews historical and industry standard methods of determining solid propellant burn rate. It identifies the advantages and disadvantages of the several methods and points out characteristics which lead to inaccuracy. The paper addresses ways to overcome the shortcomings of the various methods and presents AAD's technique for obtaining burn rate data having coefficients of variations under 0.25 percent, from 5C3-9 motor firings. This value is two to four times smaller than industry standard values. Author

ASRM DESIGN PHILOSOPHY AND MODELLING CHALLENGES
M. A. Eagar, F. W. Jordan, and L. W. Stockham *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 175-183 Sponsored by NASA. Marshall Space Flight Center (For primary document see N93-26005 09-20)
(Contract WE10E3640N)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The advanced solid rocket motor (ASRM) for the Space Shuttle presents an unusual set of modelling challenges because of its high length to diameter ratio and segmented motor design. In addition, the size of the motor limits the number of development motor firings and demands high confidence in the first time motor prediction to avoid costly motor and tooling re-design. For these reasons a design philosophy has been pursued for the ASRM that minimizes program risk and enhances ballistic confidence. This is accomplished by utilizing state of the art ballistic prediction methodology which incorporates deformed grain modelling, spatial burn rate mapping, erosive burning response, and ballistic/structural/CFD flow-grain interactions. These modelling methods are currently being validated using measured data from other motor programs, where available. Coupling these modelling methods with an aggressive prediction uncertainty assessment also allows early development of contingency plans to minimize risk and provide rapid recovery after the first demonstration motor firing (DM-1) should this become necessary. Application of these methods to the ASRM should produce increased confidence in the DM-1 motor prediction, rapid recovery potential after DM-1, and enhanced potential for program success. Author

DETERMINATION OF BURN RATE REQUIREMENTS FROM ASRM PERFORMANCE SPECIFICATIONS **c25**
S. S. Schlueter, F. W. Jordan, and L. W. Stockham *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 185-191 Sponsored by NASA. Marshall Space Flight Center (For primary document see N93-26005 09-20)
(Contract WE10E3640N)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

There are many performance specifications on a large solid rocket motor which could potentially drive burn rate accuracy requirements. This paper shows the methods used to quantify the allowable burn rate variability for the Advanced Solid Rocket Motor (ASRM). It covers the impact of flight set thrust imbalance on burn rate requirements as well as normal ballistic variability limits. The thrust imbalance restraints are evaluated in terms of both average motor burn rate variations and localized longitudinal burn rate variations. Based on this work, it is recommended that the target value for the allowable mean motor burn rate difference between motors in a flight set be 0.62 percent, and that the localized motor burn rate variability target be a three sigma value of 2 percent. The problem of accidental ignition of explosive components when exposed to radio frequency (RF) environments or radiation from other electromagnetic sources is commonly referred to as Hazards of Electromagnetic Radiation to Ordnance (HERO). One illustration of such a HERO problem is the MK 149 Phalanx ammunition, which is sensitive to RF energy over a broad range of frequencies. We have demonstrated that a potential solution to the Phalanx HERO problem consists of a semiconductor bridge (SCB) igniter that incorporates microcircuitry to protect the SCB from the RF environment. Direct RF injection and ground plane tests have demonstrated the resistance of our designs to severe RF environments. Author

FLAME STRUCTURE STUDIES OF A LEAN, 20 TORR H2/N2O/AR FLAME EMPLOYING MOLECULAR BEAM MASS SPECTROMETRY **c25**
D. C. Dayton, R. C. Sausa, and A. W. Miziolek *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 197-203 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

In this paper we report on our continued experimental efforts to investigate the structure of low pressure, burner stabilized H2/N2O/Ar flames. Coated Pt/Pt-Rh(10 percent) thermocouples and molecular beam sampling followed by quadrupole mass spectrometric detection (MB/MS) were employed to obtain temperature and species mole fraction profiles, respectively, in a fuel lean (Phi = 0.64), 20 torr H2/N2O/Ar flame. Species profiles of H2, N2O, N2, H2O, NO, O2, H, O, and OH are compared to profiles generated using a detailed flame kinetic model. The results provide a more stringent test of the detailed chemical flame model and chemical mechanism for the H2/N2O/Ar system which is presently being developed in our laboratory and will be described in a companion paper. Author

MODELING OF H2/N2O FLAMES **c25**
W. R. Anderson and C. M. Faust *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 205-213 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Efforts have continued in our laboratory to study the detailed chemical structure of gas phase flames related to solid propellant combustion. Our recent research has focused on flames of H2/N2O. The oxidizer in this flame is known to be an important intermediate in the combustion of nitramine and double-base propellants. In a previous study, the reaction mechanism to describe H2/N2O chemistry has been critically reviewed and has been tested for a stoichiometric, low pressure H2/N2O/Ar flame. Agreement between model and experiment is good. However, in order to fully test the mechanism, it must be able to model other flame conditions, as well as other experiments. In this paper this mechanism will be subjected to modeling other literature flame studies at both low and atmospheric pressures of varying stoichiometries. Species profiles as well as flame speed calculations will be presented. Preliminary conclusions regarding the formation of NO and the importance of the reaction N2O + OH = HO2 + N2 are presented. KINETIC STUDIES IN GAS-PHASE REACTION MECHANISMS IMPORTANT TO THE COMBUSTION PROCESS OF HIGH ENERGY DENSITY MATERIALS: THE H2/NO2 REACTION **c25**

R. A. Yetter, N. Ilincic, F. L. Dryer, M. Allen, and J. Gatto *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 215-223 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Kinetic experiments on mixtures of H2/NO2/N2 were performed in a variable temperature, variable pressure flow reactor over temperature, pressure, and residence time ranges of 694-944K, 1-12 atm, and 20-2000ms, respectively. Initial fuel to oxidizer ratios were varied from 0.4 to 80. Model predictions for the profiles of H2, H2O, NO2, NO, and temperature, obtained from solving the time-dependent kinetics of a detailed reaction mechanism were compared with the experimentally measured profiles. The predicted overall reaction rate was observed to be approximately 2-3 times too fast based on literature rate parameters. Reaction flux and sensitivity analyses were used to identify the rate controlling reactions. Among these reactions, the rate of H2 + NO2 = HONO + H had the largest uncertainty. Adjustment of this rate nearly within its uncertainty limits was found to yield generally good agreement between model and experiment. Author

DARK ZONE MODELING OF SOLID PROPELLANT FLAMES **c25**

J. A. Vanderhoff, W. R. Anderson, and A. J. Kotlar *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 225-237 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Modeling of the dark zone and onset of the second reaction zone (luminous flame) has been attempted for solid propellant combustion. The model is a homogeneous thermal ignition model (SENKIN) which incorporates detailed chemistry. The chemistry comes from the Miller - Bowman mechanism with other additions and modifications. Sensitivity analyses have been performed on this reaction set and the two most sensitive reactions are not well characterized. This model and reaction set has been tested on experimental data from double base and nitramine propellants. The model can predict times to the onset of a luminous flame that encompass the experimental data for double base propellants. For nitamine propellants the model predicts times slower than what is observed experimentally. However, the experimental data base for the nitramine propellants much less complete than for double base propellants and this may be a dominant factor. Nonetheless, it is clear that more work on both reaction rate measurements and dark zone diagnostics needs to be done in order to develop a fuller understanding of this combustion region. Author

DETECTION OF ATOMIC OXYGEN AND HYDROGEN IN SOLID PROPELLANT FLAMES AND PYROLYSIS GASES USING MULTIPHOTON LASER-INDUCED FLUORESCENCE **c25**

B. E. Forch *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 239-248 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Atomic oxygen and atomic hydrogen have been detected in solid propellant combustion (JA2) using two-photon laser-induced fluorescence near 225.6 nm and three-photon laser-induced fluorescence near 292 nm respectively. These atoms were also detected in pyrolysis gases generated at the propellant surface from a long-pulse Nd:YAG laser during ignition. Oxygen atom two-photon laser-induced fluorescence has been used as a probe of the ground electronic spin-orbit-split state distributions for temperature measurement. The experimentally determined distributions were fit using computer-generated synthetic spectra to yield a thermodynamic temperature of 600 +/- 70 K in laser-produced pyrolysis gases at the propellant surface and 2600 +/- 320 K in steady-state combustion at atmospheric pressure. Normalized relative intensity profiles for O and H atoms are shown in these environments and laser power dependencies for the processes are reported. Author

TOMOGRAPHIC ANALYSIS OF SIGHT INFRARED SPECTRA OF LOW PRESSURE FLAMES **c25**

Kevin L. McNesby and Robert A. Fifer *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 249-262 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Line of sight Fourier transform infrared absorption spectra through a 17 torr methane/nitrous oxide flame have been tomographically analyzed using Abel's equations. Relative absorbances for N2O, CH4, CO2, NO, and CO have been mapped for various 'slices' of the flame at different heights in the flame. Results indicate that the region of maximum NO and CO formation occurs prior to the luminous region of the flame. The technique is shown to be useful in obtaining data from systems for which line of sight data may be unusable. Author

INFRARED FIBER OPTIC DIAGNOSTIC FOR SOLID PROPELLANT COMBUSTION **c25**

J. Wormhoudt and P. L. Kebabian *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 263-268 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

We report on a program to develop and demonstrate a diagnostic technique using infrared fiber optics to probe the decomposition processes in burning gun propellant strands. The present experimental configuration involves measuring the absorption through a small gap between two embedded fibers. The gap can be filled with propellant, or left open to fill with gaseous decomposition products. Spectroscopic detection is presently achieved using pairs of band pass filters. The absorption record can be correlated with readings from an embedded thermocouple and with a high resolution video recording of the burn. The goal of this program is to develop a fast-response probe of solid phase processes which can support the development of a predictive modeling capability for gun propellant combustion. Examples of the data for atmospheric pressure burns the experiment is now producing are discussed. A full assessment of the usefulness of this technique will require further observations and analysis. Author

CONDENSED-PHASE PROCESSES DURING SOLID PROPELLANT COMBUSTION. PART 4: CHEMICAL AND MICROSCOPIC EXAMINATION OF LASER-IRRADIATED PROPELLANT SAMPLES **c25**

M. A. Schroeder, R. A. Beyer, A. Cohen, R. A. Fifer, and R. A. Pesce-Rodriquez *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 269-281 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The surfaces of laser-irradiated gun propellants have been examined by Scanning Electron Microscopic (SEM) and Fourier Transform Infrared (FTIR) microscopy; the results suggest that the laser-irradiated surfaces exhibit chemical and physical changes similar to those exhibited by the burned surfaces of extinguished propellant samples. This is consistent with the idea that the main effect of the laser beam is thermal in nature. Some possible implications of these results for combustion and for the modeling of laser ignition are discussed. Author

THERMAL DECOMPOSITION OF HMX, MONONITROSO-RDX, TNCHP AND K6 IN THE LIQUID PHASE: RESULTS FROM SIMULTANEOUS THERMOGRAVIMETRY MODULATED BEAM MASS SPECTROMETRY MEASUREMENTS **c28**

Richard Behrens, Jr. and Suryanarayana Bulusu (Army Armament Research and Development Command, Dover, NJ.) *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 283-293 Supported by U.S. Army Research Office (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The effects of physical properties and molecular conformation on the thermal decomposition kinetics of several cyclic nitramines are examined and compared to the relatively well characterized decomposition of RDX. The compounds used in the study are: octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX), hexahydro-1-nitroso-3,5 dinitro-s-triazine (ONDNTA), 1,3,5-trinitro-1,3,5-triazacycloheptane (TNCHP), and 2-oxo-1,3,5-trinitro-1,3,5-triazacyclohexane (K6). The comparisons are based on differences in the identities and temporal behaviors of the products formed during the thermal decomposition of these materials. The decomposition pathways of HMX in the liquid phase are similar to the four parallel decomposition pathways that control the decomposition of RDX in the liquid phase. Similarities and differences between HMX and RDX decomposition are discussed. The products formed during the thermal decomposition of ONDNTA arise from multiple reaction pathways. The mass spectrum of ONDNTA at 20 eV is presented. The identities and temporal behaviors of the ONDNTA decomposition products are discussed. TNCHP is thermally stable in the liquid phase. The decomposition products from TNCHP are formed via multiple reaction pathways. Decomposition through an intermediate that is the mononitroso analogue of TNCHP is observed for TNCHP. However, TNCHP does not form a stable product that is analogous to oxy-s-triazine (OST) formed in RDX or the smaller ring fragments formed in the liquid-phase decomposition of HMX. K6 is less thermally stable and the decomposition mechanism is much simpler than that of RDX, HMX and TNCHP. The thermal decomposition of K6 occurs between 150 and 180 C. The products formed during the decomposition of K6 are mainly CH2O and N2O with minor amounts or HCN, CO, NO, and NO2. Author

Decomposition and combustion of energetic materials involve processes in both condensed and gas phases. Development of reliable models for design, performance, stability, and hazard analyses requires detailed understanding of the mechanisms for both the initial condensed phase decomposition of the energetic material and the subsequent reaction of the decomposition species to form the ultimate reaction products. Those mechanisms must be described in terms of constitutive rate expressions that can be incorporated into mathematical models. The thermal decomposition of RDX has been studied by Behrens and Bulusu using Simultaneous Thermogravimetric Modulated Beam Mass Spectrometry (STMBMS). Their work provides a basis for developing some of the constitutive rate expressions that are needed in models for design, performance, stability and hazard analyses involving RDX. Behrens and Bulusu have identified four primary reaction pathways that control the liquid-phase decomposition of RDX at temperatures between 200 and 215 C, and one that controls solid-phase decomposition at temperatures below 200 C. Two of the liquid-phase pathways appear to be first order in RDX. Arrhenius parameters for the first-order rate constants were evaluated from data reported by Behrens and Bulusu. Reaction rates extrapolated to temperatures between 370 and 450 C are in good agreement with global reaction rates observed by Trott et al. using high-speed photography and laser-heated thin-film samples. Furthermore, the STMBMS results of Behrens and Bulusu appear to be consistent with condensed-phase infrared results reported by Trott et al. and Erickson et al. Author

What happens to an energetic material after it is heated, but before it begins to generate energy? Does the mechanism of the rate-limiting reaction of thermal decomposition of an energetic material affect the combustion mechanism? To find answers to such questions, RDX, as a model nitramine and an energetic material of interest to the propellant community, was heated in the isothermal-age mode of the accelerating-rate calorimeter (ARCTM) at a temperature about 20 C lower than its normal decomposition temperature. At the end of a long induction time, the chemical products formed were identified by GC-mass spectrometry. One of the well-known products and catalysts of RDX decomposition is formaldehyde. The purpose of this research was to increase the thermal stability of RDX by lengthening the induction time. The approach was to identify a chemical that would scavenge the formaldehyde formed during the induction time. The scavenger chemical and the new compound formed can not react with RDX, and the formaldehyde must be the only decomposition product that is the catalyst for this approach to work. Chemicals selected from the analytical procedures for analyzing formaldehyde were added to the cell containing RDX. Many of the chemicals chosen reacted with the RDX to shorten the induction time, but one, 2,4-dinitro-phenylhydrazine (DNPH), in small amounts lengthened the induction time by a few hours; however, crash precipitated mixtures gave short induction times. DNPH is under further investigation. A group of ammonium salts were also tested. They gave different results depending on their decomposition temperatures and products. Ammonium sulfate did not shorten the induction time but shortened the acceleratory period between the end of induction time and maximum heating rate. A possible explanation is the formation of hexamine, a product formed from ammonia and formaldehyde. Addition of hexamine to RDX gave rapid decomposition. Author

ADN PROPELLANT DIFFUSION FLAME STRUCTURE **c25**

Tim Parr and Donna Hanson-Parr *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 313-327 (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The diffusion flame structure of sandwich geometry propellants made from ADN with a variety of binders including wax, HTPB, and GAP was studied using Planar Laser Induced Fluorescence (PLIF), emission, and Mie scatter imaging, and emission and LIF spectroscopy. Flame species imaged included CN, NH, CH, NO2, NO (v=0 and v=1), and OH. Diffusion flames between ADN and all binders were clearly evident. Various lamina thicknesses were studied down to a binder layer thickness of 80 micron. Diffusion flame heights were always taller than for comparable AP sandwiches under comparable conditions, sometimes by as much as an order of magnitude. Total flame height decreased with decreasing binder lamina thickness but the dark zone height stayed relatively constant. Ignition delays decreased significantly with increasing binder energy. In comparison to neat HMX flames, ADN/binder sandwich flames were found to be taller, and to contain much less CN radicals, less NO2, more CH, and a different distribution of NO (less towards the surface but significant amounts in the burnt gas region where HMX has essentially none). The dependence of the flame structure on CO2 laser flux was investigated and the flame height did not appear to vary significantly with decreased laser flux. LIF emission spectra were monitored concurrently with PLIF using an Optical Multichannel Analyzer (OMA) which also measured flame chemiluminescence. Mie scatter images showed large apparently liquid droplets directly above the ADN laminae but little or no smoke formation in the combusting regions. Large quantities of smoke were formed only when the ADN smoldered after a test. Author

PHYSICAL AND CHEMICAL PROCESSES GOVERNING THE CO2 LASER-INDUCED DEFLAGRATION OF AMMONIUM DINITRAMIDE (ADN) **c28**

B. L. Fetherolf and T. A. Litzinger *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 329-338 (For primary document see N93-26005 09-20)

(Contract N00014-89-J-1238)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Experimental studies of the physical and chemical processes governing the CO2 laser-induced deflagration of ammonium dinitramide (ADN) are discussed. Results are presented as a function of pressure (0.1-3.0 atmospheres of argon) and incident laser heat flux (20-300 W/sq cm). Quantitative gaseous species measurements obtained by microprobe sampling and mass spectrometer analysis are presented in the form of spatial and temporal profiles. Both gas-phase temperature profiles and surface temperatures measured with fine-wire thermocouples are given. Visual observations of the laser heating event recorded with a high-magnification video recording system are described in detail. A surface melt layer was observed with tiny gas bubbles in the layer evident at pressures of one atmosphere or lower. A luminous flame was only observed when the pressure was raised to three atmospheres where a quasi-stable name was established. A significant amount of fine pale-white particles, believed to be ammonium nitrate (AN), were evolved from the melt layer when no flame existed but were not observed when a name was established. The pre-flame species measured with the microprobe/mass spectrometer (MPMS) system were, in order of descending mole fraction, H2O, N2O, N2, NO2, NH3, and NO. The flame reactions consumed N2O, NO2, and NH3, generating significant amounts of NO and H2O and smaller amounts of N2 and O2. Several temperature traces are also presented as a function of pressure and incident heat flux. The pre-flame zone temperature increased about 100 K when the pressure was raised from one atmosphere to three atmospheres. A surface temperature of 570-580 K was measured for laser heating at one atmosphere. Sporadic temperature measurements of the quasi-stable name indicated flame temperatures of 1250-1330 K. An enthalpy balance calculation using the measured name products predicted a name temperature of 1275 K. Chemical reactions governing the observed energetic behavior are proposed in an effort to interpret the experimental results in terms of possible mechanisms that depend on specific test conditions.

INTERACTIONS OF ACOUSTIC WAVES AND COMBUSTION OF HOMOGENEOUS SOLID PROPELLANTS IN ROCKET MOTORS **c28**
V. Yang and I. S. Tseng *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 347-358 (For primary document see N93-26005 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A comprehensive numerical analysis has been conducted to study the effect of propellant combustion on the acoustic waves in a solid rocket motor. The theoretical model is based on the full conservation equations of mass momentum, energy, and species concentration, with consideration of variable properties and finite-rate chemical kinetics. Turbulence closure is achieved rising a modified k-epsilon two-equation model which takes into account the wall injection effect arising from surface combustion of the propellant. Results indicate that the strong temperature gradient near the propellant surface has a significant effect on the behavior of the acoustic field. The unsteady flow motions may interact intimately with gas-phase chemical reactions when the characteristic time scales of these two mechanisms are closely matched, as evidenced by the large amplitude of temperature fluctuations within the flame zone.

This paper describes an experimental investigation of the flow turning loss in solid propellant rocket motors experiencing an axial instability. It is caused by the interaction of the radially directed flow of combustion products that leaves the burning propellant surface with the axial acoustic field. This study utilized an experimental setup designed to simulate the flow conditions near the burning surface of a solid propellant motor in an unstable rocket motor. It consisted of a rectangular duct with a wall mounted injector that supplied a flow into the duct to simulate the flow of combustion products leaving the propellant surface. Acoustic drivers were used to excite acoustic oscillations that simulated an axial instability in the duct. The mean and acoustic velocities as well as the acoustic pressure oscillations were measured throughout a control volume encompassing a region where the flow turning loss was expected to occur. The measured data were then used to evaluate the various terms that appear in an acoustic stability equation, developed earlier under this program, that contains the various loss and gain terms including the flow turning loss. Experiments were performed to determine the effects of the injection and mean flow Mach numbers, the amplitude of the oscillation, and the location of the burner relative to the standing axial acoustic wave upon the magnitude of the flow turning loss in the investigated control volume. The measurements show that the magnitude of the flow turning loss is strongly dependent upon the injection velocity and the location of the injection point relative to the standing acoustic wave, which is in agreement with the predictions of relevant models. Finally, measured data were used to specify the boundary conditions in a previously developed numerical simulation of the experimental setup. The simulation's predictions were found to be in good agreement with the measured flow turning loss.

Flame structure for nitramines deflagrating under an oscillatory heat flux were measured as a function of forcing frequency and phase angle in an attempt to validate the quasi-steady state assumption for the gas phase response. For HMX deflagration the flame height response function was found to closely track the burn rate response function so the quasi-steady state assumption appears valid, at least for nitramines.

A theoretical and experimental investigation is being conducted on the unsteady combustion of homogeneous energetic materials under dynamic radiant heating conditions. A newly developed pulsed laser-recoil technique was used to study a fine oxidizer AP-HTPB composite and an M10 propellant. The linear stability analysis of steady burning in the presence of a constant radiant flux is also presented. Steady burning rate and temperature measurements are reported and are used to interpret the unsteady results. Large differences were observed between 5 micron and 25 micron

thermocouple traces. The larger thermocouples were unable to resolve the surface reaction zone. The frequency response of the fine oxidizer AP-HTPB composite exhibited two resonance peaks that are attributed to the thermal layer and the reaction zone for the low and high frequency peaks, respectively. This was verified by the measured time scales of the thermal layer and the surface reaction layer using the 5 micron thermocouples. The location of the surface on the temperature trace was confirmed by using an additional wire of the propellant to measure the current between it and the thermocouple. For this fine oxidizer AP-HTPB composite, at these conditions, the assumption of a quasi-steady surface reaction zone is clearly violated at frequencies as low as 50 Hz. These results illustrate that detailed information can be obtained using the laser recoil method that clarify the important structure of burning solids. These results further suggest that more detailed models that relax the quasi-steady assumption should be developed. Author

DYNAMIC BURNING RATE MEASUREMENTS OF METALIZED COMPOSITE PROPELLANTS USING THE LASER-RECOIL TECHNIQUE **c25**

M. Q. Brewster, M. H. Hites, and S. F. Son *In* JHU, 29th JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1992 p 387-397 Sponsored by Thiokol Corporation (For primary document see N93-26005 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The combustion mechanisms of metalized AP/HTPB/Al composite propellants have been investigated using a newly developed pulsed laser-recoil technique to measure dynamic propellant burning rate. The results demonstrate that aluminum has a stronger influence on the combustion of AP/HTPB propellants than is indicated by the small changes observed in the macroscopically steady burning rate or the mean burning rate during macroscopically unsteady combustion. The addition of 18 percent Al in AP/HTPB propellant causes only a 10 percent increase in the mean burning rate at 1 atm pressure but a 300 percent increase in the amplitude of the laser-perturbed fluctuating component of the burning rate at 40 Hz. The prominent resonance observed at 40 Hz does not correspond to the classical thermal conduction-relaxation mechanism but appears to be related to the processes of unsteady accumulation, agglomeration, ignition, and departure of aluminum at the burning surface of the propellant. It was also found that a small quantity (1 percent) of chopped Kevlar fibers effectively damped the 40 Hz resonance and increased the steady burning rate at pressures below 5.4 MPa (800 psia). These observations are attributed to a flame-holding effect of the Kevlar fibers which protrude through the surface of the propellant and anchor the partially premixed, leading edge flame near the propellant surface. SRB ENVIRONMENT EVALUATION AND ANALYSIS. VOLUME 1: REDESIGNED SRB FLIGHT HEATING EVALUATION Final Report

William K. Crain Sep. 1991 379 p

(Contract NAS8-37891)

(NASA-CR-192517; NAS 1.26:192517; RTR-213-01-Vol-1) Avail: CASI HC A17/MF A03

Following the Space Shuttle STS-51L disaster on January 28, 1986, a considerable redesign effort was launched on the Solid Rocket Booster. This effort culminated in three instrumented flights, STS-26R, 27R, and 29R, beginning in September of 1989. Aeroheating data were obtained on these flights in the form of pressure, heat flux, and gas temperature probe measurements. These data were analyzed from an ascent and reentry heating point of view. The flight data were verified, compared with historic and theoretical results, and scaled to design. Impact of these results on the current design environment set was assessed and recommendations made. This report documents this effort. Author

Contract NAS8-37891 was expanded in late 1989 to initiate analysis of Shuttle plume induced environments as a result of the substitution of the Advanced Solid Rocket Booster (ASRB) for the Redesigned Solid Rocket Booster (RSRB). To support this analysis, REMTECH became involved in subscale and full-scale solid rocket motor test programs which further expanded the scope of work. Later contract modifications included additional tasks to produce initial design cycle environments and to specify development flight instrumentation. Volume 3 of the final report describes these analyses and contains a summary of reports resulting from various studies. Author

REMTECH SSME NOZZLE DESIGN TPS Final Report

Steven A. Bancroft, Carl D. Engel, and John E. Pond Sep. 1990 114 p

(Contract NAS8-36151)

(NASA-CR-192516; NAS 1.26:192516; RTR-113-03) Avail: CASI HC A06/MF A02

Thermal damage to the Space Shuttle Main Engine (SSME) aft manifold Thermal Protection System (TPS) has been observed for flights STS-8 through STS-13. This damaged area is located on the ME2 and ME3 and extends over a region of approximately one square foot. Total failure or burn-through of the TPS could lead to severe thermal damage of the SSME manifold and loss of an engine nozzle necessitating nozzle replacement causing significant schedule delays and cost increases. Thermal damage to the manifold can be defined as a situation where the manifold temperature becomes greater than 1300 F; thereby causing loss of heat treatment in the nozzle. Results of Orbiter/nozzle wind tunnel tests and Hot Gas Facility tests of the TPS are presented. Aerothermal and thermal analysis models for the SSME aft manifold are discussed along with the flight predictions, design trajectory and design environment. Finally, the TPS design concept and TPS thermal response are addressed. Author

SRB ENVIRONMENT EVALUATION AND ANALYSIS. VOLUME 2: RSRB JOINT FILLING TEST/ANALYSIS IMPROVEMENTS Final Report, Sep. 1989 - Sep. 1991

E. C. Knox and G. Hamilton Woods Sep. 1991 81 p

(Contract NAS8-37891)

(NASA-CR-192518; NAS 1.26:192518; RTR-213-01-Vol-2) Avail: CASI HC A05/MF A01

Following the Challenger accident a very comprehensive solid rocket booster (SRB) redesign program was initiated. One objective of the program was to develop expertise at NASA/MSFC in the techniques for analyzing the flow of hot gases in the SRB joints. Several test programs were undertaken to provide a data base of joint performance with manufactured defects in the joints to allow hot gases to fill the joints. This data base was used also to develop the analytical techniques. Some of the test programs were Joint Environment Simulator (JES), Nozzle Joint Environment Simulator (NJES), Transient Pressure Test Article (TPTA), and Seventy-Pound Charge (SPC). In 1988 the TPTA test hardware was moved from the Utah site to MSFC and several RSRM tests were scheduled, to be followed by tests for the ASRM program. REMTECH Inc. supported these activities with pretest estimates of the flow conditions in the test joints, and post-test analysis and evaluation of the measurements. During this support REMTECH identified deficiencies in the gas-measurement instrumentation that existed in the TPTA hardware, made recommendations for its replacement, and identified improvements to the analytical tools used in the test support. Only one test was completed under the TPTA RSRM test program, and those scheduled for the ASRM were rescheduled to a time after the expiration of this contract. The attention of this effort was directed toward improvements in the analytical techniques in preparation for when the ASRM program begins. Author

A Doppler-resolved, pulsed laser Rayleigh scattering diagnostic has been developed to obtain local flowfield velocity measurements at the exit plane of a low thrust hydrogen/oxygen rocket engine operating in a high-altitude test facility. Fiber optic signal collection was employed to obtain the forescatter and backscatter Doppler shifts necessary to resolve the axial and radial velocity components. A radial profile was obtained by traversing the collection probes along the beam path at the nozzle exit. The results are compared with theoretical predictions from a full Navier Stokes model (RK/RPLUS). Significant discrepancies between the measured and predicted axial velocity profiles are observed, in terms of both magnitude and character. Radial velocity measurements exhibit excellent agreement with predictions near the centerline but show some departure off-axis. The discrepancies between theory and experiment are potentially the result of enhanced mixing between the core and fuel-film region beyond that predicted, and/or flow stratification between the hydrogen and oxygen injected into the central core region. APPLICATION OF THE SAHA EQUATION TO HIGH TEMPERATURE (GREATER THAN OR EQUAL TO) ROCKET EXHAUST Final Report, period ending Aug. 1992
Robert T. Nachtrieb Nov. 1992 148 p
(AD-A261648; PL-TR-92-3042) Avail: CASI HC A07/MF A02

Using the Saha equations and spectroscopic constants, the computer program in this report calculates the species populations of diatomic molecules, neutrals, ions, and electrons in a plasma. The code considers the equilibrium of a two-element, chemically reacting plasma, by calculating the partition function for each species. By rederiving theoretically, as the JANAF tables do, the thermodynamic properties of a rocket propellant, but using extended excitation levels, the program can estimate (above 6000 K) performance of advanced propulsion concepts. An interagency Nuclear Safety Working Group (NSPWG) was chartered to recommend nuclear safety policy, requirements, and guidelines for the Space Exploration Initiative (SEI) nuclear propulsion program. These recommendations, which are contained in this report, should facilitate the implementation of mission planning and conceptual design studies. The NSPWG has recommended a top-level policy to provide the guiding principles for the development and implementation of the SEI nuclear propulsion safety program. In addition, the NSPWG has reviewed safety issues for nuclear propulsion and recommended top-level safety requirements and guidelines to address these issues. These recommendations should be useful for the development of the program's top-level requirements for safety functions (referred to as Safety Functional Requirements). The safety requirements and guidelines address the following topics: reactor start-up, inadvertent criticality, radiological release and exposure, disposal, entry, safeguards, risk/reliability, operational safety, ground testing, and other considerations. This paper presents the status of technology program planning to develop those Nuclear Electric Propulsion technologies needed to meet the advanced propulsion system requirements for planetary science missions in the next century. The technology program planning is based upon technologies with significant development heritage: ion electric propulsion and the SP-100 space nuclear power technologies. Detailed plans are presented for the required ion electric propulsion technology development and demonstration. Closer coordination between space nuclear power and space electric propulsion technology programs is a necessity as technology plans are being further refined in light of NEP concept definition and possible early NEP flight activities. We investigate the performance of a nonlinear estimation scheme applied to the estimation of several parameters in a performance model of the Space Shuttle Main Engine. The nonlinear estimator is based upon the extended Kalman filter which has been augmented to provide estimates of several key performance variables. The estimated parameters are directly related to the efficiency of both the low pressure and high pressure fuel turbopumps. Decreases in the parameter estimates may be interpreted as degradations in turbine and/or pump efficiencies which can be useful measures for an online health monitoring algorithm. This paper extends previous work which has focused on off-line parameter estimation by investigating the filter's on-line potential from a computational standpoint. In addition, we examine the robustness of the algorithm to unmodeled dynamics. The filter uses a reduced-order model of the engine that includes only fuel-side dynamics. The on-line results produced during this study are comparable to off-line results generated previously. The results show that the parameter estimates are sensitive to dynamics not included in the filter model. Off-line results using an extended Kalman filter with a full order engine model to address the robustness problems of the reduced-order model are also presented. Author

Infrared Background Signature Survey spectra of exhaust gases from attitude controlling liquid-bipropellant thrusters, taken from onboard space shuttle on mission STS-39 in connection with the Orbiter Environment Experiment, are analyzed. The high-resolution multichannel sensor viewed both the expanding combustion products near the engine and through the volume where these high kinetic energy molecules react with atmospheric species. Its segments of data over about half the spectrum range between 2.5 and 17.5 microns showed primarily H2O and CO2 vibrational and rotational radiation, with no other emission features unambiguously identifiable. A comparison with synthetic spectra compiled from HITRAN gave a reasonably close fit to excited-state temperatures, 800-1200K, while the absolute radiances were in some cases below those that would result from the column-concentrations of exhaust species predicted by CONTAM because of collision limiting. These spectral radiances quantify the optical contamination resulting from Shuttle Orbiter's routine reaction control engine firings. DTIC

DC-DC POWER CONVERTER RESEARCH FOR ORBITER/STATION POWER EXCHANGE

M. Ehsani May 1993 56 p

(Grant NAG9-431)

(NASA-CR-192939; NAS 1.26:192939) Avail: CASI HC A04/MF A01

This project was to produce innovative DC-DC power converter concepts which are appropriate for the power exchange between the Orbiter and the Space Station Freedom (SSF). The new converters must interface three regulated power buses on SSF, which are at different voltages, with three fuel cell power buses on the Orbiter which can be at different voltages and should be tracked independently. Power exchange is to be bi-directional between the SSF and the Orbiter. The new converters must satisfy the above operational requirements with better weight, volume, efficiency, and reliability than is available from the present conventional technology. Two families of zero current DC-DC converters were developed and successfully adapted to this application. Most of the converters developed are new and are presented. Derived from text

(NASA-CR-191084; E-7628; NAS 1.26:191084) Avail: CASI HC A04/MF A01

This paper summarizes preliminary experimental and theoretical research that was directed towards the study of quasisteady-state power flow in a large, un-optimized, multi-megawatt coaxial plasma thruster. The report addresses large coaxial thruster operation and includes evaluation and interpretation of the experimental results with a view to the development of efficient, steady-state megawatt-class magnetoplasmadynamic (MPD) thrusters. SPACE TRANSPORTATION BOOSTER ENGINE THRUST CHAMBER TECHNOLOGY, LARGE SCALE INJECTOR Final Report

J. A. Schneider Feb. 1993 456 p Original contains color illustrations

(Contract NAS8-37470)

(NASA-CR-192531; NAS 1.26:192531) Avail: CASI HC A20/MF A04; 1 functional color page

The objective of the Large Scale Injector (LSI) program was to deliver a 21 inch diameter, 600,000 lbf thrust class injector to NASA/MSFC for hot fire testing. The hot fire test program would demonstrate the feasibility and integrity of the full scale injector, including combustion stability, chamber wall compatibility (thermal management), and injector performance. The 21 inch diameter injector was delivered in September of 1991. Author

Avail: CASI HC A03/MF A01

Pitot pressures and flow angles are measured in the plume of a nozzle flowing nitrogen and exhausting to a vacuum. Total pressures are measured with Pitot tubes sized for specific regions of the plume and flow angles measured with a conical probe. The measurement area for total pressure extends 480 mm (16 exit diameters) downstream of the nozzle exit plane and radially to 60 mm (1.9 exit diameters) off the plume axis. The measurement area for flow angle extends to 160 mm (5 exit diameters) downstream and radially to 60 mm. The measurements are compared to results from a numerical simulation of the flow that is based on kinetic theory and uses the direct-simulation Monte Carlo (DSMC) method. Comparisons of computed results from the DSMC method with measurements of flow angle display good agreement in the far-field of the plume and improve with increasing distance from the exit plane. Pitot pressures computed from the DSMC method are in reasonably good agreement with experimental results over the entire measurement area. Author

VICKERS INDENTATION HARDNESS OF STOICHIOMETRIC AND REDUCED SINGLE CRYSTAL TiO2 (RUTILE) FROM 25 TO 800 C

Christopher DellaCorte and Daniel L. Deadmore Apr. 1993 10 p

(RTOP 505-63-1A)

(NASA-TM-105959; E-7464; NAS 1.15:105959) Avail: CASI HC A02/MF A01

The indentation microhardness of stoichiometric and reduced single crystal rutile (TiO2) from 25 to 800 C is presented in this paper. The results serve two main purposes. One is to assess the effect of rutile's stoichiometry on its hardness. The other is to test recently suggested theory on solid lubrication with sub Stoichiometric rutile in an effort to better understand shear controlled phenomenon. Microhardness was measured using a Vickers diamond indentor on both vacuum and hydrogen reduced single crystal rutile from 25 to 800 C. The results indicate that stoichiometry and temperature have a pronounced effect on rutile's hardness. The measured effects lend support to theory on solid lubrication by enhanced crystallographic slip and suggest that solid lubricant materials may be produced by careful atomic level tailoring (stoichiometry control). STRESS DISTRIBUTION IN COMPOSITE FLATWISE TENSION TEST SPECIMENS

Curtis A. Scott (Ohio Aerospace Inst., Brook Park.) and J. Michael Pereira Mar. 1993 12 p

(RTOP 505-63-1B)

(NASA-TM-106074; E-7683; NAS 1.15:106074) Avail: CASI HC A03/MF A01

A finite element analysis was conducted to determine the stress distribution in typical graphite/epoxy composite flat wise tension (FWT) specimens under normal loading conditions. The purpose of the analysis was to determine the relationship between the applied load and the stress in the sample to evaluate the validity of the test as a means of measuring the out-of-plane strength of a composite laminate. Three different test geometries and three different material lay ups were modeled. In all cases, the out-of-plane component of stress in the test section was found to be uniform, with no stress concentrations, and very close to the nominal applied stress. The stress in the sample was found to be three-dimensional, and the magnitude of in-plane normal and shear stresses varied with the anisotropy of the test specimen. However, in the cases considered here, these components of stress were much smaller than the out-of-plane normal stress. The geometry of the test specimen had little influence on the results. It was concluded that the flat wise tension test provides a good measure of the out-of-plane strength for the representative materials that were studied. Author

MONITORING DAMAGE GROWTH IN TITANIUM MATRIX COMPOSITES USING ACOUSTIC EMISSION

J. G. Bakuckas, Jr., W. H. Prosser, and W. S. Johnson Mar. 1993 46 p

(RTOP 763-23-45-85)

(NASA-TM-107742; NAS 1.15:107742) Avail: CASI HC A03/MF A01

The application of the acoustic emission (AE) technique to locate and monitor damage growth in titanium matrix composites (TMC) was investigated. Damage growth was studied using several optical techniques including a long focal length, high magnification microscope system with image acquisition capabilities. Fracture surface examinations were conducted using a scanning electron microscope (SEM). The AE technique was used to locate damage based on the arrival times of AE events between two sensors. Using model specimens exhibiting a dominant failure mechanism, correlations were established between the observed damage growth mechanisms and the AE results in terms of the events amplitude. These correlations were used to monitor the damage growth process in laminates exhibiting multiple modes of damage. Results revealed that the AE technique is a viable and effective tool to monitor damage growth in TMC.

DYNAMIC DEFORMATIONS AND ANALYSIS OF A METAL MATRIX COMPOSITE Ph.D. Thesis

Brad Stewart Altman 1992 174 p

Avail: Univ. Microfilms Order No. DA9303231

Deformation of a model particulate reinforced metal-matrix composite is studied over strain rates ranging from 10(exp -3) to 10(exp 3)/s in compression and 10(exp -3) to 10(exp 2)/s in tension. The material is 2014 aluminum alloy with alumina particulate reinforcement of 10 and 20 volume percent. Tests are also performed on 2014 aluminum to provide a baseline for comparison. Micromechanical models are used to predict material response. All tested specimens are examined via scanning and transmission electron microscopy to characterize the differences in microstructural evolution and failure modes. Dissert. Abstr.

METHOD FOR PROVIDING EMI/EMP HARDENING AND BREAKDOWN PROTECTION IN COMPOSITE MATERIALS Patent

David S. Dixon, inventor (to Navy) and James V. Masi, inventor (to Navy) 22 Dec. 1992 6 p Filed 20 Jun. 1990

(AD-D015638; US-Patent-5,173,871; US-Patent-Appl-SN-544298) Avail: US Patent and Trademark Office

A method of forming a composite material for EMI/EMP hardening protection that has a predictable EM shielding performance in terms of penetration depth is provided. A base material is doped with a predetermined volume fraction of filler particles such that the base material forms a separating contact region between each pair of adjacent filler particles. An electrical equivalent circuit for a filler particle pair and separating contact region is used to represent electrical properties associated with the filler particle pair and separating contact region. A network equivalent impedance of the base material doped with the filler particles is generated using the electrical equivalent circuit. The network equivalent impedance, dielectric constants of the base material and the filler particles, and the predetermined volume fraction of filler particles are used to predict the EM shielding performance of the base material doped with the filler particles in terms of penetration depth. FRACTURE OF AN ELLIPTICAL INCLUSION AND ITS IMPLICATIONS FOR THE PROPERTIES OF SHORT FIBER COMPOSITES Ph.D. Thesis

Gunay Anlas 1992 147 p

Avail: Univ. Microfilms Order No. DA9301772

A model is developed to analyze the effect of fiber fracture on the elastic properties of short fiber composites. Tensile test specimens were prepared from 26.6 percent, 12.9 percent fiber V(f) samples. The specimens were tested in tension to failure. Fractography and optical metallography performed in the plane of the reinforcement showed fragmentation of fibers which eventually led to overall material failure. To model the fiber failure in an infinite matrix, the problem of crack and elliptical inclusion interaction is solved. The crack in the inclusion is formulated in terms of a distribution of dislocations. The dislocation solution is used as a Green's function and resulting singular integral equations are solved numerically. Stress intensity factors are tabulated for both a crack inside and outside the elastic elliptical inclusion. The specific case of a completely cracked inclusion is solved. The solution of a completely cracked inclusion is then used in a micromechanics model of the damaged composite. The energy dissipated through the opening of the crack in the inclusion is calculated and used in a self consistent method to find the overall effective moduli of the composite. The results are given for the prediction of the effective moduli, E and mu, of the 2-D composite containing cracked fibers which are randomly distributed and oriented. Dissert. Abstr.

ANALYSIS OF MATRIX DAMAGE IN UNIDIRECTIONAL COMPOSITES Ph.D. Thesis

V. G. Mukunda 1992 107 p

Avail: Univ. Microfilms Order No. DA9224675

The fracture behavior of composites in the presence of a flaw needs to be studied in order to exploit their vast structural potential. Thus analytical models were developed using shear lag concepts to determine the displacement and stress field in a fiber-reinforced unidirectional composite with various damage configurations. The effect of friction on the initiation and growth of longitudinal matrix damage is studied for center-noticed specimens. A consistent shear lag constitutive relationship is employed to take into account the load carrying capacity of the matrix. The results show that the introduction of friction within the matrix split in the form of a closed crack retards the split growth. Further, this model is employed to study the splitting mechanism in edge-noticed unidirectional composite specimens. The model predictions are shown to agree with the experimental results. Finally, a comparison is made between the classical shear lag model and a consistent shear lag model for different damage configurations. This comparison shows that the classical shear lag model predicts acceptable results if the ratio of Young's modulus of the fiber to the Young's modulus of the matrix is large. However, for composites in which fiber and matrix are comparable, the consistent shear lag formulations yields better results, especially in predicting some of the matrix-dominant failure modes. (DE93-007504; UCRL-JC-111215; CONF-920890-1) Avail: CASI HC A03/MF A01

Al 5182/Al 6061-25 vol. percent SiCp and ultrahigh carbon (1.8 percent C) steel/brass (70 percent Cu-30 percent Zn type) laminates were prepared by press-bonding stacks of alternating layers of the component materials. Press bonding of these materials required consideration of the flow stresses of the component materials and the interlayer friction. Tensile properties and fracture toughness were measured for different processing conditions of surface oxide descaling, layer thickness, and heat treatment. Descaling of the surface oxide prior to the press-bonding was found to eliminate premature delamination along interfaces resulting in an increased yield strength and tensile ductility. Reduction in the layer thickness brought an increase in the tensile ductility for both laminates and a decrease in yield strength and fracture toughness for the Al laminate. The T6 heat treatment on the Al laminate induced a substantial increase in the yield and tensile strength but a decrease in tensile ductility. Fracture surface morphology indicated evidences of local delamination, crack blunting and bridging. Fracture toughness measured in the crack arrester and crack divider orientation showed a substantial enhancement over that of the Al 6061-SiCp or UHCS components. DOE

THE DAMAGE, REPAIR AND DESIGN OF FIBER COMPOSITE STRUCTURAL MATERIALS Ph.D. Thesis
Fa-De Jack Chu 1992 210 p
Avail: Univ. Microfilms Order No. DA9303716

Three aspects of the repair of fiber reinforced composite materials were examined in this study. First, the in-plane compression damage of four typical fiber composite materials was studied, and different repair strategies were explored. Second, an optimum composite sheet design for least damaged by buckling and easiest to repair was studied. Third, the curing and resulting properties of the inter facial region between an anhydride-cured epoxy adhesive and E-glass fibers/vinyl ester matrix, which is critical to the quality of the repair, was investigated. For none of the four typical fiber composite materials subjected to in-plane compression do all of the load carrying fibers break, and those that do are usually in easily removable layers. Moreover, the behavior of each material was relatively consistent. As a result, a new repair strategy is proposed in which no more of the load-carrying fibers are removed from the damage zone than are broken. For the two laminated materials, a transition in failure mode from tensile to shear was found as the effective gage length of the specimen decreased. This suggests that the composite structure can be designed to relieve the applied load in desired locations and with benign failure modes. In the second part, ten composite materials with different fiber stacking sequences were subjected to in-plane compression. Three failure modes were dominant: shear, delamination buckling, and flexural failure. The volume of damage occurring in the 0 deg - fiber plies decreased and the repair efficiency increased in the sequence: shear, flexural, delamination buckling failure. With respect to the amount of damage and repair strength recovery, it is best to have the composite structure designed to fail in delamination buckling when failure is inevitable. In the third part, model systems were used to simulate the interfacial region between adhesive and adherent. These involved curing the adhesive against a FTIR-ATR plate and against adherent material ground to a fine powder to greatly increase its surface area. The increase in reaction heat and To suggest that there is no interfacial problem for an anhydride-cured epoxy adhesive used with E-glass/vinyl ester composite materials.

DESIGN AND VALIDATION OF OPTIMAL EXPERIMENTS FOR ESTIMATING THERMAL PROPERTIES OF COMPOSITE MATERIALS Ph.D. Thesis
Ramsis Taktak 1992 156 p
Avail: Univ. Microfilms Order No. DA9303056

Composite materials have gained an unprecedented interest in the last twenty years. Their superior strength-to-weight ratios have made them very popular with aerospace, automotive, boat, biomedical, and even the sporting goods industry. The radar-absorbing quality of composite materials, together with their strength-to-weight ratios, make these attractive for military applications. When used in air and space vehicles, composite materials are exposed to harsh thermal loads. An understanding of the thermal behavior of these materials became necessary. The thrust of this work is the estimation of two thermal parameters: thermal conductivity and volumetric heat capacity. There are three main parts to the current research; each part describes a different aspect of estimating these thermal properties. The first part compares two experimental research paradigms pertaining to the effect of the temperature rise on the estimated parameters during transient parameter estimation experiments. The second part of this research relates to optimal experiments. Two one-dimensional experiments for finite and semi-infinite geometries are shown to be superior to some previously published ones. The two experimental parameters of heating time and cooling time are especially of interest for these experiments. An optimal value is obtained for each parameter using a selected optimality criterion. A two-dimensional case is studied following the same methodology. Design curves relating the optimality criterion to the geometry and directional properties of the material of interest are obtained. The analytical results of the optimal experiments pertaining to the finite one-dimensional geometry are verified using an experimental technique developed by Garnier and Beck. In the third part of this research, the thermocouple-induced errors, which are usually small quantities, are quantified using an analytical approach. Finite difference and finite element methods are supplemented because of their limitations in calculating small differences. Some experiments are then designed and implemented in order to verify these analytical results. The results of the three different parts of this research have great potential for improving the estimation of composite material thermal properties.

DETERMINATION OF THE ELASTIC CONSTANTS OF COMPOSITE MATERIALS FROM ULTRASONIC GROUP VELOCITY MEASUREMENTS
Lin Niu 1992 180 p
Avail: Univ. Microfilms Order No. DA9236006

A nondestructive test procedure based on the ultrasonic point-source-receiver (PS/PR) technique is described in this thesis. In the procedure group velocity data determined from the signals detected in an anisotropic composite specimen is processed to recover the matrix of elastic constants of the material. The composites are modeled as homogeneous, elastically anisotropic materials, whose elastic constants or stiffness are related to the speeds of the elastic waves propagating in them. It is shown that the wave arrivals in the PS/PR waveforms detected in the far field from the source correspond closely to the group velocities of plane waves propagating in the associated directions. Since there is no explicit equation relating the group velocities and the material stiffness, the inverse problem of recovering the elastic constants from the wavespeed data is solved by an algorithm consisting of an inner minimization loop to determine the wave normals and an outer optimization loop to recover the elastic constants. The solution to the forward problem is used to identify

the arrivals of specific wave modes in the signals detected for a particular source/receiver geometry. A procedure for processing the arrivals of quasi-transverse waves propagating along directions through cuspidal regions of the wave surface is also developed. To evaluate the operation of the procedure, the sensitivity of the algorithm for recovering the elastic constants from perturbed wavespeed data was determined. Also considered was the use of only quasi-longitudinal wavespeed data to recover a subset of the material's elastic constants. Experiments were carried out using the PS/PR measurement configuration. The point source was a monopolar force with a step-unloading time-function which was obtained from the fracture of a small-diameter glass capillary on the surface of a specimen. Such a source generates ultrasonic signals that exhibit a broad angular spectrum in the material. The point-receiver was a small-aperture capacitive transducer whose output is proportional to the local vertical displacement of the medium over a broad bandwidth. The processing algorithm was first evaluated using wavespeed data obtained in a single crystal specimen of zinc, a material whose matrix of elastic constants is known. Then a number of composite specimens, including several uni-directional fiber-reinforced and cross-ply laminate composite plates, were tested. For transversely isotropic materials, the full set of elastic constants were recovered. For the orthotropic materials, a partial set of the elastic constants was recovered. The results were compared with those obtained using conventional ultrasonic measurement procedures. Dissert. Abstr.

DAMAGE-SURVIVABLE AND DAMAGE-TOLERANT LAMINATED COMPOSITES WITH OPTIMALLY PLACED PIEZOELECTRIC LAYERS Final Report, Aug. 1989 - Dec. 1992
S. P. Joshi and W. S. Chan 13 Nov. 1992 151 p
(Contract DAAL03-89-G-0090)
(AD-A260879; ARO-27167.3-EG-SM) Avail: CASI HC A08/MF A02

The main objective of the research is to assure that the embedded sensors/actuators in a smart laminated composite structure are damage-survivable and damage-tolerant. The research requires development of analytical and computational techniques and tools together with the experimental evaluation of smart composite structural elements. An understanding of electroelastic constitutive behavior is critical to predicting the response of a structure with embedded piezoelectric material. Our research efforts in this area have produced a concise formulation of linear constitutive relations that have been extended to the nonlinear case. The CDA (Composite Delamination Analysis) and SDACLP (Static and Dynamic Analysis for Composite Laminated Plates) packages have been modified to incorporate piezoelectric coupling in a quasi-3D and plane stress analysis. EFFECT OF WATER IMMERSION ON FIBER/MATRIX ADHESION
Thomas Juska Jan. 1993 19 p
(Contract F33615-89-C-0532)
(AD-A260704; CDNSWC/SME-92/38) Avail: CASI HC A03/MF A01

A study was made on the effect of water immersion on fiber/matrix adhesion in composites. Representatives of the four main classes of continuous fiber composites were tested: glass/thermoset, carbon/thermoset, glass/thermoplastic, and carbon/thermoplastic. Water conditioning was done by immersion in 50 C distilled water. The only class of composites degraded by water was glass-reinforced thermoplastics. However, carbon-reinforced vinyl esters, a subset of the carbon/thermoset class, appear to have weak fiber/matrix bonds when dry, and these bonds are further degraded by water. In both cases, immersion in water hydrolyzed the interfacial bonds and caused large, irrecoverable property reductions. DTIC

NUMERICAL SIMULATION OF DAMAGE AND PROGRESSIVE FAILURES IN COMPOSITE LAMINATES USING THE LAYERWISE PLATE THEORY Ph.D. Thesis
Yeruva Satyanarayana Reddy 1992 148 p
Avail: Univ. Microfilms Order No. DA9237155

The failure behavior of composite laminates is modeled numerically using the Generalized Layerwise Plate Theory (GLPT) of Reddy and a progressive failure algorithm. The Layerwise Theory of Reddy assumes a piecewise continuous displacement field through the thickness of the laminate and therefore has the ability to capture the interlaminar stress fields near the free edges and cut outs more accurately. The progressive failure algorithm is based on the assumption that the material behaves like a stable progressively fracturing solid. A three-dimensional stiffness reduction scheme is developed and implemented to study progressive failures in composite laminates. The effect of various parameters such as out-of-plane material properties, boundary conditions, and stiffness reduction methods on the failure stresses and strains of a quasi-isotropic composite laminate with free edges subjected to tensile loading is studied. The ultimate stresses and strains predicted by the Generalized Layerwise Plate Theory (GLPT) and the more widely used First Order Shear Deformation Theory (FSDT) are compared with experimental results. The predictions of the GLPT are found to be in good agreement with the experimental results both qualitatively and quantitatively, while the predictions of FSDT are found to be different from experimental results both qualitatively and quantitatively. The predictive ability of various phenomenological failure criteria is evaluated with reference to the experimental results available in the literature. The effect of geometry of the test specimen and the displacement boundary conditions at the grips on the ultimate stresses and strains of a composite laminate under compressive loading is studied. The ultimate stresses and strains are found to be quite sensitive to the geometry of the test specimen and the displacement boundary conditions at the grips. The degree of sensitivity is observed to depend strongly on the lamination sequence. The predictions of the progressive failure algorithm are in agreement with the experimental trends. Finally, the effect of geometric nonlinearity on the first-ply and ultimate failure loads of a composite laminate subjected to bending load is studied. The geometric nonlinearity is taken in to account in the von Karman sense. It is demonstrated that the nonlinear failure loads are quite different from the linear failure loads, depending on the lamination sequence, boundary conditions, and span-to-depth ratio of the test specimen. Further, it is shown that the First order Shear Deformation Theory (FSDT) and the Generalized Layerwise Plate Theory (GLPT) predict qualitatively different results. Dissert. Abstr.

INELASTIC BEHAVIOR OF THERMOPLASTIC COMPOSITES Ph.D. Thesis
Ilsup Chung 1992 123 p
Avail: Univ. Microfilms Order No. DA9301279

The mechanical behaviors of AS4 reinforced PEKK-based composites were studied. These new thermoplastic composite system developed by Du Pont exhibit pronounced nonlinear and time dependent behaviors. To characterize the inelastic behavior, classical plasticity and creep theory have been adopted and modified for the orthotropic case by using a one-parameter potential function. The elastic-plastic behavior of LDF(TM) AS-4/PEKK system employing aligned, long discontinuous fiber reinforced composites has been studied in comparison with the continuous fiber reinforced counterpart. A dual mode plastic potential action was employed to model the plastic behaviors of these composites at room and elevated temperatures up to 177 C. A one-parameter failure criterion was also applied to predict the failure strength. Off-axis coupon specimens were used to measure the failure strength and generate stress-strain curves from which the elastic-plastic properties were extracted. It was observed that the elastic-plastic performance and strength of LDF(TM) are as good as those of the continuous fiber system. A creep model for orthotropic material has been developed based on the same one-parameter potential function. The material constants were determined by using uniaxial creep tests of off-axis coupon specimens. In terms of effective stress and effective creep strain, the anisotropic creep behavior was described by a stress dependent master creep curve irrespective of loading direction relative to fiber orientation. This model was implemented into classical laminate theory to predict the creep behavior of composite laminate, and compared with experimental data of (+/- 45)4s laminate specimens. The influence of thermal stress was included. The micromechanical approach also was tried to model the inelastic behavior of continuous fiber reinforced composites. The fiber was assumed to be orthotropically elastic, and the matrix to conform to the classical elastic-plasticity and creep theories. For the so called mechanics of material type of approach, a representative volume element assuming simplified distribution of stress and strain was employed,

and numerical prediction was compared with other existing models or experiments. Dissert. Abstr.

INVESTIGATION AND MODELING OF PENETRATION PROCESS FOR COMPOSITE LAMINATES IMPACTED BY A BLUNT-ENDED PROJECTILE Ph.D. Thesis
Shi-Wei Ricky Lee 1992 143 p
Avail: Univ. Microfilms Order No. DA9301336

The objectives of the present research are to investigate the penetration process and to develop a corresponding computational model for composite laminates subjected to the impact of a blunt-ended projectile. Three specimen configurations were arranged to study the effect in dimensions. A series of static punch tests were conducted to characterize the load-displacement relation. The progressive damage mechanisms were identified by terminating the tests at various check points along the static punch curve. X-ray radiography, optical microscopy, and acoustic microscopy were used to inspect the tested specimens. Delamination and plugging were found to be the two major damage modes in the penetration process. It was further observed that the delamination is initiated by some matrix cracks. However, the plugging appears to be a localized behavior, and the experimental data reveal that the load for plug formation is independent of the span of the specimen. High velocity impact experiments were also performed for dynamic penetration. In general, the major damage modes resemble those observed in the static punch tests. Besides the striking velocity, the residual velocity of the projectile was measured as well for specimens subjected to complete penetration. The ballistic limit of composite laminates can be calculated from the difference between the initial and the residual kinetic energy of the projectile. An axisymmetric finite element analysis was employed to model the penetration process of composite laminates. An apparent modulus scheme together with the fracture mechanics concept was adopted to simulate the major damage events during penetration. The static punch curve was incorporated into the present analysis as a penetration criterion so that the ballistic limit of composite laminates can be estimated. The validity of the proposed model is verified by the agreement between experimental data and computational results. It is concluded that the ballistic limit can be predicted by the present model without performing dynamic impact tests. Dissert. Abstr.

FINITE ELEMENT MICROMECHANICS MODELING OF INELASTIC DEFORMATION OF UNIDIRECTIONALLY FIBER-REINFORCED COMPOSITES Ph.D. Thesis
Su-Yen Hsu 1992 190 p
Avail: Univ. Microfilms Order No. DA9306156

A convenient and efficient algorithmic tangent matrix approach has been developed for 3-D finite element (FE) analysis using the endochronic theory without a yield surface. The underlying algorithm for integrating the endochronic constitutive equation was derived by piecewise linearization of the plastic strain path. The approach was employed to solve a micromechanics boundary value problem of a cyclically loaded unidirectional boron / 6061 aluminum composite. All the FE results consistently demonstrate superior numerical stability and efficiency of the proposed method. Extensions of the method to endochronic plasticity with a yield surface and to the plane stress case are also presented. A simple and unified weak formulation and its convenient FE implementation have been proposed. The weak formulation is valid for any doubly periodic model under uniform 3-D macro-stress, and serves as a common rational foundation of different FE approaches. The algorithmic tangent matrix approach for the endochronic theory has been incorporated into the FE formulation to model isothermal, rate-independent plastic macro-deformation of unidirectional fibrous composites with idealized two-phase microstructure and backed-out inelastic matrix properties. Methods for determining inelastic material parameters of the matrix have been established. Numerical results for a B/6061 Al composite subjected to on-axis and off-axis monotonic tensile loadings are in good agreement with experimental data. The micromechanics model also shows the potential for quantitative characterization of complicated cyclic behavior. Finally, some effects of model geometry on overall plastic response of the B/6061 Al composite are discussed from the viewpoint of theoretical experimental correlation. Dissert. Abstr.

QUANTIFYING DISTRIBUTED DAMAGE IN COMPOSITES VIA THE THERMOELASTIC EFFECT Ph.D. Thesis
Brian Joseph Mahoney 1992 215 p
Avail: Univ. Microfilms Order No. DA9231211

A new approach toward quantifying transverse matrix cracking in composite laminates using the thermoelastic effect is developed. The thermoelastic effect refers to the small temperature changes that are generated in components under dynamic loading. Two models are derived, and the theoretical predictions are experimentally verified for three types of laminates. Both models include damage-induced changes in the lamina stress state and lamina coefficients of thermal expansion conduction effects, and epoxy thickness. The first model relates changes in the laminate TSA signal to changes in longitudinal laminate stiffness and Poisson's ratio. This model is based on gross simplifying assumptions and can be used on any composite laminate layup undergoing transverse matrix cracking. The second model relates TSA signal changes to longitudinal laminate stiffness, Poisson's ratio, and microcrack density for (0 sub p/90 sub q)sub s and (90 sub q/0 sub p)sub s cross-ply laminates. Both models yield virtually identical results for the cross-ply laminates considered. A sensitivity analysis is performed on both models to quantify the effects of reasonable property variations on the normalized stiffness vs. normalized TSA signal results for the three laminates under consideration. The results for the cross-ply laminates are very insensitive, while the (+/- 45)sub 5s are particularly sensitive to epoxy thickness and longitudinal lamina coefficient of thermal expansion. Experiments are conducted on (0 sub 3/90 sub 3)sub s and (90 sub 3/0 sub 3)sub s Gl/Ep laminates and (+/- 45)sub 5s Gr/Ep laminates to confirm the theoretical developments of the thesis. There is a very good correlation between the theoretical predictions and experimental results for the Gl/Ep laminates. There is also a good correlation for the (+/- 45)sub 5s Gr/Ep laminates; however, additional testing must be done to confirm the acceptability of the assumption that the epoxy thickness is equal to zero. Dissert. Abstr.

LOW-VELOCITY IMPACT OF COMPOSITE SANDWICH PLATE Ph.D. Thesis
Chung-Lin Wu 1992 172 p
Avail: Univ. Microfilms Order No. DA9301415

Much work has been done on impact resistance and impact tolerance of composite sandwich panel. However, there is no research that predicts the impact force history of a composite sandwich plate and the corresponding stress distribution. Thus, the objectives of this research are to establish a model to analyze force response during the impact, application of a suitable failure criterion to explain the damage mechanism on the face sheets, and use the linear fracture mechanics to predict the propagation of delamination. Through the understanding of failure processing, a new type of core material and sandwich structure are designed to improve the damage resistance of core and face sheets. A finite element procedure was performed to predict the impact force history. Two types of impactors are used on this study. For the spherical impactor, plate finite element is adopted. For cylindrical impactor, Plane strain finite element was employed. For plate finite element, a new model treated facing as two independent Mindlin plates, core material resisted transverse normal strain and transverse shear deformation, and Impactor was assumed as a rigid body. The impact force history is determined experimentally and compared with the predicted values for foam core and honeycomb core sandwich plate. Damage mechanisms are observed by X-ray radiograph and cross-sectional optic microscopic photographs. Maximum principle stress criterion is chosen to predict the onset of matrix cracking. Fracture mechanics combined with nodal release technique is used to predict the propagation of interface delamination. Design of new core construction and the introduction of film adhesive between the 0/90 interfaces are utilized to improve the damage inside the face laminate and core section. Basic material properties tests and impact tests are performed on both tradition and new core construction. A nonlinear materials behavior for film adhesive is employed to study the effect of this tough layer on outset loading of matrix cracking and growth of interface delamination. Dissert. Abstr.

DAMAGE AND FAILURE ANALYSIS ON CONTINUOUS

FIBER-REINFORCED POLYMER COMPOSITES Ph.D. Thesis
Fuh-Sheng Chen 1992 178 p
Avail: Univ. Microfilms Order No. DA9306102

In chapter one, the damage that accompanies flexural deformation of a unidirectional glass fiber reinforced polyphenylene sulfide composite was examined by acoustic emission (AE) and scanning electron microscopy (SEM). The flexural stress-strain curve was nominally linear to about 1.0 percent strain, but the onset of damage detectable by AE occurred at 0.3 percent strain. Two peaks in the AE amplitude distribution were observed at 35dB and 60dB. Low amplitude events were detected along the entire length of the specimen. SEM observations suggested that these events arose from matrix cracking and fiber debonding. High amplitude events occurred primarily in the region of highest flexural stress between the inner loading points, they were attributed to fracture of glass fibers on the tension side and surface damage on the compressive side. In chapters two and three, the effects of the matrix modulus on the compressive failure mechanisms in flexure of unidirectional glass fiber reinforced thermoplastic Hytrel composites has been studied. An increase in the matrix Young's modulus leads to a change in the failure mode from cooperative fiber microbuckling to delamination splitting microbuckling. Cooperative fiber microbuckling is a catastrophic phenomenon without significant damage occurring in the composite system prior to the abrupt failure. Fibers are buckled both in the plane and normal to the plane of the compression surface. Delamination splitting microbuckling is associated with matrix splitting and consists of gradual accumulation of localized surface delaminations followed by buckling of fiber bundles. The transition in the mechanisms of flexural failure is semi-quantitatively explained by considering the criterion for each of the failure modes. The failure strength for cooperative fiber microbuckling is controlled by the shear modulus of the composite which is linear related to the Young's modulus of the matrix, while the failure strength for delamination splitting microbuckling is controlled by the composite shear strength which is not strongly affected on the Young's modulus of the matrix. Because the critical failure stresses have different dependencies on the matrix modulus, a transition from cooperative fiber microbuckling to delamination splitting microbuckling occurs as the matrix modulus increases. Dissert. Abstr.

THE CORROSION OF METAL MATRIX COMPOSITES Ph.D. Thesis
Sarah L. Coleman 1991 243 p
Avail: Univ. Microfilms Order No. BRDX97176

The corrosion characteristics of aluminium alloys containing a number of ceramic reinforcements has been investigated. The reinforcements included continuous carbon and Nicalon fibers, short alumina (Saffil) fibers and silicon carbide particulate. The matrix metals consisted of aluminium, an Al-7Si-0.5Mg casting alloy and an Al-4Cu-1.5Mg precipitation hardening alloy. The composites were fabricated either by liquid metal infiltration (LMI), squeeze casting or powder metallurgy. The corrosion studies have been carried out using natural immersion and accelerated corrosion methods such as the cyclic polarization test. Special attention has been focused on a double cyclic polarization technique. This has proved to be invaluable for predicting the susceptibility of MMC to pitting attack, good correlation having been found between pitting and protection potentials derived from this method and those from open circuit potential measurements made under natural immersion conditions. The electrochemical studies have been combined with detailed microstructural analysis. Examination of the corroded surfaces and sections through the corroded material has been carried out using optical, scanning electron microscopy (SEM), transmission electron microscopy (TEM) and energy dispersive spectroscopy (EDS). These have enabled the sites of corrosion attack to be identified, such as fiber/matrix interfaces, secondary and intermetallic phases and pores and crevices caused by poor infiltration during fabrication. The MMC containing the most electrically conducting fiber, carbon, appeared to suffer the greatest degrees of attack at fiber/matrix interfaces. The effect was not wholly due to a galvanic action, but to the presence of a reaction product, aluminium carbide, Al4C3, which reacted strongly with water. The geometry of the reinforcement was found to effect the propagation of corrosion pits. Continuous fibers tended to act as barriers and channel the corrosion along the fibers, whereas the Saffil short fibers and SiC particulate allowed lateral growth of corrosion pits. The chemical composition of the metal matrix was found to play an important role regarding corrosion sites. In particular intermetallics containing iron, present largely as an impurity, proved detrimental to the corrosion resistance and caused enhanced attack of the surrounding metal due to a microgalvanic action. The method of composite manufacture also affected the corrosion process and was related to pores caused by poor infiltration in regions of densely-packed fibers. Dissert. Abstr.

TRANSFORMATION PLASTICITY AND FRACTURE BEHAVIOR OF CERIA-TZP/ALUMINA COMPOSITES Ph.D. Thesis
Jyh-Shiarn Cherng 1992 226 p
Avail: Univ. Microfilms Order No DA9303712

A systematic study of transformation plasticity, R-curve behavior, and the strength characteristics in Ce-TZP/Al2O3 composites was conducted to explore the microstructural effects on the mechanical properties of transformation-toughened ceramics. Microstructures with different degrees of tetragonal phase connectivity and grain sizes were obtained by various amounts of alumina addition and different sintering temperatures. The test range, in terms of stress space for transformation plasticity and strength characteristics, was extended beyond those found in the literature. Four point bending and compression tests with a superimposed hydrostatic pressure constituted the experimental methods for that purpose. R-curves were measured by cycled loading-unloading in four point bending of fatigue-precracked specimens. Results from such a study indicate that a Mohr-Coulomb type of yield criterion can be used to describe the deformation behavior of the Ce-TZP/Al2O3 composites. Both alumina addition and grain refinement expand the yield surface outward. The evolution of the transformation curve from one with distinct two stages to one with continuously gradual transformation is facilitated by alumina addition or applied pressure. On the other hand, grain refinement favors perfectly plastic deformation but suppresses the burst-like transformation during cooling. Both the height and shape of the R-curve depend on the microstructure. The addition of alumina decreases K(sub 0) (slightly), K(sub m), and delta-K, while grain refinement increases K(sub 0) (slightly), but decreases Km, and delta-K. Above a certain alumina content, the R-curve exhibits a peak followed by extensive crack growth due to subcritical crack growth. The increase of crack resistance, delta-K, can be attributed to transformation toughening as the data fit well with a model proposed by Chen. An analysis of the bend strengths of the Ce-TZP/Al2O3 composites reveals a ductile-brittle-ductile-brittle transition map which serves as a framework to guide future materials development of transformation toughened zirconia. A simple model was also developed to correlate strength with the R-curves in these materials. Dissert. Abstr.

IN-SITU ULTRASONIC C-SCANNER
S. C. Galea and D. S. Saunders Nov. 1992 20 p
(AD-A261113; ARL-TR-4; DODA-AR-006-634) Avail: CASI HC A03/MF A01

Monitoring damage growth in composite materials during axial fatigue tests, without removing the specimen from the loading machine, is normally achieved using techniques such as shadow moire fringe, X-radiography, thermography, or residual stiffness measurements. All except the last method provide an indication of the extent of damage. However, none of these techniques provide information on the through-the-thickness location of the damage. For detailed inspection, the specimen would normally be removed from the testing machine and C-scanned using an immersion scanning system. This Technical Report describes an in-situ C-scanning apparatus, based on the time-of-flight C-scanning technique developed at DSTO-ARL, for monitoring damage growth while the specimen is still located in the testing machine. This system uses a semi-impervious membrane and water couplant which allows the specimen to be scanned without full immersion of the specimen and the probe. Set-up procedures and operational details are also described. Comparisons of in-situ C-scans with immersion tank C-scans and optical macrographs of cross-sectioned specimens were undertaken, in order to validate the new system. DTIC

ACTIVE CONTROL OF NITINOL-REINFORCED STRUCTURAL COMPOSITES Final Report, 15 Aug. 1989 - 14 Aug. 1992
A. Baz 12 Oct. 1992 170 p LIMITED REPRODUCIBILITY: More than

20% of this document may be affected by microfiche quality
(Contract DAAL03-89-G-0084)
(AD-A261062; ARO-27216.6-EG-SM) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The rapidly growing technology of the shape memory nickel-titanium alloy (NITINOL) is utilized to develop SMART composite materials that are capable of adapting intelligently to internal and external excitations. The NITINOL fibers are embedded into the composite matrix, at optimal locations and orientations, to sense and control the static and dynamic characteristics of the resulting SMART composite. With such built-in self-inspecting and controlling capabilities, the performance of the SMART composite can be optimized and tailored, in real time, to match changes in the operating conditions. Emphasis has been placed on controlling the static, dynamic, and thermal characteristics of anisotropic NITINOL-reinforced beams. Furthermore, the sensing capabilities of the NITINOL fibers are investigated by using them as distributed strain gages to monitor the physical and modal displacements of NITINOL-reinforced composites. Finite element models are developed to predict structural stability and the static, dynamic, and thermal behavior of NITINOL-reinforced composite beams. The theoretical predictions of these models are validated experimentally. DTIC

Progress has been made in characterizing the parameters needed to achieve selective electrodeposition onto a nanostructured surface and in techniques and procedures needed to create a nanoheterostructure, a class of composite solid-state/solid-state and biomolecular/solid-state materials with nanometer-scale structure. A newly created device called a minicell, a minielectrochemical cell, proved to be very successful in terms of dealing with the small substrate size (usually less than 20 mm squared) on which our nanostructures are formed. We found that a properly designed electrochemical cell for these experiments should have the working-reference and working-counter electrode distances the same. It should also use a counter electrode with a large surface area exposed to the electrolyte, and one which is located over the whole working electrode, so that deposition occurs smoothly and uniformly across the entire substrate surface. CHARACTERIZATION OF AEROSPACE GRADE RESINS AND COMPOSITES THROUGH PRESSURIZED VOLUMETRIC DILATOMETRY Final Report, Dec. 1990 - Jul. 1992
J. D. Russell and D. B. Curliss Jul. 1992 91 p
(AD-A260794; WL-TR-92-4062) Avail: CASI HC A05/MF A01

The technique of Pressurized Volumetric Dilatometry has been used to characterize the specific volume changes over pressure and temperature of several state-of-the-art aerospace thermoplastic and thermoset resins and composites and several pitch precursors for carbon-carbon composites. The materials studied were poly(etheretherketone) PEEK; HTA; HTX; PBO/PEEK; 3501-6 epoxy; AS4/3501-6 prepreg; IM7/8551-7A prepreg; IM7/5250-2 prepreg; Ashland Oil pitches A-240, A-60, A-70, and A-80; Reilly Coal Tar; and Mitsubishi's AR Synthetic Mesophase Pitch. Accurate and reproducible Pressure-Volume-Temperature (PVT) data have been yielded by this technique. Important processing information such as Tg(P), CTE(TP), T-(P), Tc(P), cure shrinkage, and other phase changes which give rise to volume changes can be extracted from the PVT data. DTIC

THERMOMECHANICAL RESPONSE OF SHAPE MEMORY COMPOSITES Technical Report
James G. Boyd and Dimitris C. Lagoudas 18 Jan. 1993 18 p LIMITED REPRODUCIBILITY: Availability: Document partially illegible
(Contract DAAL03-92-G-0123)
(AD-A260828; ARO-30378.4-EG-URI) Avail: CASI HC A03/MF A01

The Mori-Tanaka micromechanics method is used to predict the effective properties of composite materials consisting of a polymer matrix reinforced by a fiber made of a transformation shape memory effect (SME) material. The composite response is plotted for combinations of the following scenarios: (1) isothermal longitudinal and transverse stress input, (2) stress-free thermal loading, (3) constant fiber thermoelastic properties, and (4) thermoelastic fiber properties that vary with the martensite volume fraction. For the case of an isothermal stress input, the composite transformation stress, the maximum transformation strain, and the hysteresis are all reduced vis-a-vis the monolithic SME material. In contrast to a monolithic SME material, stress-free thermal loading of a SME composite can produce a transformation strain. It is shown that closed form solutions for the effective martensite and austenite start temperatures can be derived, that they are sensitive to the stress-free reference temperature of the fiber, and that the stress-free austenite and martensite start temperatures are higher than those of the monolithic SME material. (Contract N00014-91-C-0067)
(AD-A260978) Avail: CASI HC A03/MF A01

This program aims at improving current methods of lifetime assessment by building in the characteristics of the micro-mechanisms known to be responsible for damage and failure. The broad approach entails the integration and, where necessary, augmentation of the micro-scale research results currently available in the literature into a macro-scale model with predictive capability. In more detail, the program will develop a set of hierarchically structured models at different length scales, from atomic to macroscopic, at each level taking as parametric input the results of the model at the next smaller scale. In this way the known microscopic properties can be transported by systematic procedures to the unknown macro-scale region. It may not be possible to eliminate empiricism completely, because some of the quantities involved cannot yet be estimated to the required degree of precision. In this case the aim will be at least to eliminate functional empiricism. DTIC

DAMAGE DETECTION AND MITIGATION OF COMPOSITE STRUCTURES USING SMART MATERIALS
Abu S. Islam and Kevin Craig 18 Jan. 1993 12 p
(Contract DAALO3-92-G-0123)
(AD-A261121; ARO-30378.7-EG-URI) Avail: CASI HC A03/MF A01

This paper reports the results of an ongoing experimental program for damage assessment and mitigation of composite structures using smart materials. One consequence of all damage to a composite structure is a change in its stiffness. This change in stiffness is measured by modal analysis which can be carried out using piezoelectric films as both sensor and actuator on the structure member. It is shown that the presence of damage can be detected by the change in natural frequencies and the location of the damage can be detected from the ratio of changes in frequencies between two successive modes. Experiments are now being

carried out using healthy and damaged composite beams of rectangular cross section with piezoceramic sensors and actuators. In this paper experimental results of damage detection will be described in detail.

THERMAL EXPANSION MEASUREMENTS OF POLYMER MATRIX COMPOSITES AND SYNTACTICS Final Report
Louise C. Sengupta and William A. Spurgeon Apr. 1992 15 p
(MTL-TR-92-27) Avail: CASI HC A03/MF A01

The coefficients of thermal expansion (CTE) of various polymer matrix materials were measured using a thermal mechanical analyzer. The measurements include a set of standard materials used as calibration materials for the instrument. The data for the base polymers, syntactics, and E and S-2 glass-reinforced polyester matrix composites were obtained in the temperature range from -77 to 120 C. The results for all of the polymeric materials, especially for the epoxy and epoxy syntactic (above 65 C), are nonlinear. The CTE of the syntactics were reduced by a factor of approximately 2 for the base resins. The data taken for the glass-reinforced composites show peaks and/or humps in the thermal expansion. These features are believed to be from the formation of voids within the plies of the composite laminate. The irregular behavior of the thermal expansion was minimized by thermal annealing under load conditions, whereas annealing in free-space does not significantly dampen this behavior. The thermal expansion of the material appears to be directly related to the fiber loading.

A slurry of BSAS glass powders is cast into tapes which are cut to predetermined sizes. Mats of continuous chemical vapor deposition (CVD)-SiC fibers are alternately stacked with these matrix tapes. This tape-mat stack is warm-pressed to produce a 'green' composite which is heated to burn out organic constituents. The remaining interim material is then hot-pressed to form a BSAS glass-ceramic fiber-reinforced composite.

ELECTROSTATIC FIBER SPREADER Patent Application
Jonathan M. Peritt, inventor (to Navy), Richard Everett, inventor (to Navy), and Alan Edelstein, inventor (to Navy) 5 Nov. 1992 14 p
(AD-D015677; US-Patent-Appl-SN-788018) Avail: CASI HC A03/MF A01

A fiber spreader is discussed. The spreader is designed to reduce the fiber damage that occurs during spreading. The fiber spreader includes a thin electrically grounded support sheet for supporting a layer of fibers on one surface. The fibers supported on the support sheet are guided by guide rollers past at least one corona discharge region at which the fibers are spread. A motor driven spool advances the support sheet past the corona discharge region. The fibers are attached to the support sheet by an electrostatic attraction. The guide rollers are positioned so as to provide at least one region in which the sheet and the fibers are physically separated to allow for the uniform spreading of the fibers. After the fibers are spread the fibers and the support sheet are united again and collected on a motor-driven spool.

SMART STRUCTURAL COMPOSITES WITH PIEZOELECTRIC MICRO-CONSTITUENTS Final Report, Sep. 1989 - Dec. 1992
Nisar Shaikh Dec. 1992 16 p
(Contract DAAL03-89-G-0086)
(AD-A260970; ARO-27198.1-MS-SM) Avail: CASI HC A03/MF A01

The research culminated into the feasibility of smart structural composite materials, in which the microstructure is modified with the introduction of a piezoelectric constituent. Greater success was achieved in the sensing aspect of smart properties, enabling the material to have an inherent property of health monitoring. By sensing and quantifying elastic strain, the material can monitor its dynamic state (vibration), degradation and damage. In actuation, the material is readily suitable for active vibration control and manipulative damping. One out-growth of the results was an active fibrous sensor, which offers a readily viable alternative to a passive fiber-optic sensor as it is marred with breakage problems. A new concept of piezoelectric emission, analogous to acoustic emission, emerged which imparts the material ability to sense stress waves. This ability can be used to locate the regions of delamination and local fractures through fabrication to operational life of structure. Techniques were developed for deposition of thin piezoelectric (ZnO) film on carbon and metal fibers. Sensing and actuation properties were imparted into carbon fiber composites. The results demonstrated self-sensing of strain and damage measurement in beam and shell elements. The concept is ready for technological advancement and application.

PROCESSING AND PROPERTIES OF SILICON CARBIDE REINFORCED REACTION BONDED SILICON NITRIDE COMPOSITES Final Report, 1 Sep. 1988 - 30 Sep. 1992
John S. Haggerty and Shanti Nair 30 Nov. 1992 49 p
(Contract DAAL03-88-K-0099)
(AD-A260570; ARO-25202.1-MS) Avail: CASI HC A03/MF A01

Reaction formed ceramic materials have not approached potential levels of utilization because of historically poor properties and the lack of familiarity by potential users. Research with reaction bonded silicon nitride (RBSN) has shown that reduced processing temperatures and times, high purities, net-shape fabrication, and improved properties can be achieved simultaneously with this class of materials if they are processed carefully by rather conventional techniques. Distinct from conventional high performance ceramics, reaction formed ceramics typically contain relatively high levels of residual porosity. As is true of conventional ceramics, superior properties are feasible with porous ceramics only if the microstructural characteristics of all final phases are precisely controlled; the major difference for the porous ceramics is that the pore structure must be as carefully controlled as is required for the solid phases in a high quality conventional ceramic material.

(Contract N00014-91-J-1274)
(AD-A261226; UMR-FDB-28) Avail: CASI HC A03/MF A01

The role of water and other contaminants like salt water, isooctane, and ethylene glycol on neat resin, composites, and friction materials have been investigated. The maximum solvent uptake and the diffusion coefficient of the solvent in these systems were determined and the experimental data was fitted to a Fickian model. The nature of the diffusion process was determined in each case and deviations from Fickian behavior were accounted for. For the neat resin and the composites, the diffusion coefficients of the liquids were of the order of 10(exp -10) sq cm/sec. After exposure to these contaminants, mechanical properties of all the systems were determined and a general degradation in properties were

found. The flexural strength and fracture toughness showed reduction in values while the flexural modulus was not affected. DTIC

This final report documents a 3-D computational and experimental investigation into the mechanics of roughening a brittle matrix by incorporating long brittle fibers. Computationally, small scale failure mechanisms ahead of a crack are explicitly modeled and merged with a continuum representation of the farfield outside the process zone. Particular attention is given to the interfacial decohesion and frictional slipping near the tip of a matrix crack which is impinging upon an inclusion. The surface integral and finite element (SIFEH) method, which employs the principle of superposition to combine the best features of two powerful numerical techniques, provides an extremely flexible and efficient computational platform for modeling linear elastic fractures near material inhomogeneities. Applications to general 3-D fracture growth in multimaterial media demonstrate the capabilities of the computational technique and are also described. The computational simulation is being guided by laboratory experiments. Crack growth observations made on a model (micro-) structure comprising a glass rod embedded in a cement matrix show the toughening mechanisms of crack pinning and crack bridging in operation. In a second experiment, interfacial slip evolution was modeled experimentally for planar bimaterial interfaces. This combined experimental and numerical program has provided insight into optimal combinations of the key parameters (e.g. residual stresses at interface, friction coefficient, strength of fibers) to maximize toughness. THERMALLY INDUCED STRESSES IN A COMPOSITE EXPOSED TO FIRE M.S. Thesis
Edward A. Faxlanger, Jr. Dec. 1992 98 p
(AD-A261714) Avail: CASI HC A05/MF A02

This thesis investigates the behavior of graphite/epoxy composites subjected to fire as may occur on the decks of naval aircraft carriers. The analytical model consists of two parts: one for the determination of the temperature field within the composite due to a fire, and the other for determining the stresses within the composite due to the temperature field. Both problems are provided one-dimensional finite element models. Appropriate failure criteria are incorporated to predict the survivability of composites in various fire environments. Parametric studies were performed and the results are presented in both graphical and tabular form. DTIC

FAILURE CONSIDERATIONS IN COMPOSITE SYSTEMS BASED ON 3D MICROMECHANICAL STRESS FIELDS, PART A Final Technical Report
E. S. Folias Dec. 1992 326 p
(Grant AF-AFOSR-0351-90)
(AD-A261698; AFOSR-93-0076TR-Pt-A) Avail: CASI HC A15/MF A03

In this investigation, a systematic 3D micromechanics approach is used to model a composite. The fibers are assumed to be cylindrical inclusions which are periodically embedded into a matrix plate. A three dimensional analysis is used in order to capture any edge effects which may be present. A set of fundamental key problems has been identified and their respective solutions for the displacement and stress fields are then used in order to provide us with some answers to the following fundamental questions: transverse strength, longitudinal strength, residual stresses due to thermal expansion mismatch, modeling of fiber matrix interface, edge effects. The 3D results are then used to first identify critical locations where failure, due to fracture, is most likely to initiate and second to derive fracture criteria for crack initiation at the local level. The criteria reveal the dependence of the composite strength on the material properties, the local cell geometry, the ratio of the fiber volume fraction, the ratio of fiber radius to fiber length and finally the applied mechanical and/or thermal loads. METAL MATRIX COMPOSITE ANALYZER (METCAN): THEORETICAL MANUAL
P. L. N. Murthy and C. C. Chamis Feb. 1993 36 p
(RTOP 510-01-50)
(NASA-TM-106025; E-7588; NAS 1.15:106025) Avail: CASI HC A03/MF A01

This manuscript is intended to be a companion volume to the 'METCAN User's Manual' and the 'METAN Demonstration Manual.' The primary purpose of the manual is to give details pertaining to micromechanics and macromechanics equations of high temperature metal matrix composites that are programmed in the METCAN computer code. The subroutines which contain the programmed equations are also mentioned in order to facilitate any future changes or modifications that the user may intend to incorporate in the code. Assumptions and derivations leading to the micromechanics equations are briefly mentioned. Author (revised)

INTERFACE ENGINEERING IN OXIDE FIBER/OXIDE MATRIX COMPOSITES Annual Report, 1 Mar. 1992 - 28 Feb. 1993
K. K. Chawla 28 Feb. 1993 45 p
(Contract N00014-89-J-1459)
(AD-A261705) Avail: CASI HC A03/MF A01

In earlier work it was shown that fiber roughness is a very important parameter along with the thermal mismatch between the components. PRD-166 fiber, used so far, is a very rough fiber. Saphikon, single crystal alpha-alumina, is a relatively smooth fiber, but very expensive due to its processing cost. A new polycrystalline alumina fiber, Nextel 610, has recently become available. Due to its smoother surface than that of PRD-166 fiber, this fiber can be a good reinforcement candidate in oxide/oxide composites. Microstructural and mechanical characterization of Nextel 610 fiber was performed. The tensile strength of Nextel 610, after exposure to 900 C, 1100 C, and 1300 C was determined using a two-parameter Weibull distribution. It was observed that the primary reason for the loss of the fiber strength was the grain growth. DTIC

IN-PROCESS CURE MONITORING OF COMPOSITES VIA FIBER-OPTIC FLUORESCENCE Final Report, Apr. 1989 - Jul. 1992
C. S. Sung and N. H. Sung 23 Oct. 1992 3 p Prepared in cooperation with Tufts Univ., Medford, MA
(Contract DAAL03-89-K-0081)
(AD-A261712; ARO-26571.4-MS) Avail: CASI HC A01/MF A01

The objective of the research was to develop in-situ cure monitoring technique based on intrinsic and extrinsic chemical sensors using fiber optic fluorescence method for epoxy and polyimide and to use such a fiber-optic method to investigate fiber surface effects on epoxy structure and cure kinetics. As an extrinsic cure sensor, p,p'-diamino azobenzene (DAA) shows sensitive fluorescence intensity enhancement as a result of reaction with epoxide. It was implemented for in-situ cure monitoring of bulk epoxy cured with diaminodiphenyl sulfone (DDS) at high cure temperatures (140-180 C) using fiber optic fluorescence instrument, using an internal standard dye to calibrate the intensity. The intrinsic fluorescence excitation spectra of DDS was found to show sensitive spectral shifts with cure. This result was also implemented with real composites (carbon or glass fiber reinforced prepregs) in actual cure environment by fiber optic fluorescence instrument, by taking into account the effect of temperature on the spectral position. A PREMIXED LAMINAR FLAME INTERACTING WITH A VORTEX RESULTING IN FLAME STRETCH AND QUENCHING Ph.D. Thesis
William Lafayette Roberts 1992 185 p
Avail: Univ. Microfilms Order No. DA9303811

A laminar axisymmetric vortex is interacted with laminar premixed flame in order to gain insight into the fundamentals of turbulent combustion. The interaction is visualized with Mie scattering tomography and planar laser induced fluorescence to determine the effect of the vortex on the flame. The vortex can have no effect, it can wrinkle the flame, it can cause a pocket of reactants to be formed, or the vortex can stretch the flame and cause local flame quenching. Disappearance of the reaction zone, as evidenced by the absence of superequilibrium OH fluorescence, was an excellent indicator of flamelet quenching. The size and strength of the vortex is varied to allow a combustion diagram to be constructed, which shows the borders between the above four regimes as a function of nondimensional vortex size and strength. The fuel was also varied to study thermodiffusive effects, as characterized by the Lewis number. The results show that flame quenching depends strongly on the temperature of the burnt gas. The Karlovitz number at the onset of quenching for a lean methane-air flame is defined as the nondimensional vortex strength divided by the nondimensional size of the vortex and was found to be as low as 0.1 for the larger diameter vortices and increased with decreasing vortex size. This is an order of magnitude lower than generally assumed. Lewis number effects are also quantified by considering the correlation between regions of high curvature and OH fluorescence intensity. Dissert. Abstr.

COARSENING OF A QUIESCENT ELECTRORHEOLOGICAL FLUID I: EXPERIMENT
James E. Martin, Judy Odinek, and Thomas C. Halsey (Chicago Univ., IL.) 1992 9 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC04-76DP-00789)
(DE93-006776; SAND-92-2639C; CONF-921101-87) Avail: CASI HC A02/MF A01

A real-time, two-dimensional light scattering study of the evolution of structure in a concentrated electrorheological fluid during the 'liquid-solid' phase transition is reported. After particle chaining along the electric field lines, strong light scattering lobes appear at a finite scattering wavevector q orthogonal to the field lines, and then brighten as they move to $q = 0$. This indicates the existence of an unstable concentration fluctuation that signifies the segregation of chains into columns. In fact, the observed growth kinetics of the characteristic length, as well as the form of the structure factor, are qualitatively similar to two-dimensional spinodal decomposition in a system with a conserved order parameter. During the last decade there has been a rapid upturn in interest in reactive distillation. The chemical process industry recognizes the favorable economics of carrying out reaction simultaneously with distillation for certain classes of reacting systems, and many new processes have been built based on this technology. Interest is also increasing by academics and software vendors. Systematic design methods for reactive distillation systems have only recently begun to emerge. In this report we survey the available design techniques and point out the contributions made by our group at the University of Massachusetts. DOE

MEASUREMENTS OF SOOT FORMATION AND HYDROXYL CONCENTRATION IN NEAR CRITICAL EQUIVALENCE RATIO PREMIXED ETHYLENE FLAME
Michael Andrew Inbody Mar. 1993 497 p
(Grant NAG3-1038; RTOP 537-02-20)
(NASA-CR-191099; E-7696; NAS 1.26:191099) Avail: CASI HC A21/MF A04

The testing and development of existing global and detailed chemical kinetic models for soot formation requires measurements of soot and radical concentrations in flames. A clearer understanding of soot particle inception relies upon the evaluation and refinement of these models in comparison with such measurements. We present measurements of soot formation

and hydroxyl (OH) concentration in sequences of flat premixed atmospheric-pressure C2H4/O2/N2 flames and 80-torr C2H4/O2 flames for a unique range of equivalence ratios bracketting the critical equivalence ratio (phi(sub c)) and extending to more heavily sooting conditions. Soot volume fraction and number density profiles are measured using a laser scattering-extinction apparatus capable of resolving a 0.1 percent absorption. Hydroxyl number density profiles are measured using laser-induced fluorescence (LIF) with broadband detection. Temperature profiles are obtained from Rayleigh scattering measurements. The relative volume fraction and number density profiles of the richer sooting flames exhibit the expected trends in soot formation. In near-phi(sub c) visibility sooting flames, particle scattering and extinction are not detected, but an LIF signal due to polycyclic aromatic hydrocarbons (PAH's) can be detected upon excitation with an argon-ion laser. A linear correlation between the argon-ion LIF and the soot volume fraction implies a common mechanistic source for the growth of PAH's and soot particles. The peak OH number density in both the atmospheric and 80-torr flames declines with increasing equivalence ratio, but the profile shape remains unchanged in the transition to sooting, implying that the primary reaction pathways for OH remain unchanged over this transition. Chemical kinetic modeling is demonstrated by comparing predictions using two current reaction mechanisms with the atmospheric flame data. The measured and predicted OH number density profiles show good agreement. The predicted benzene number density profiles correlate with the measured trends in soot formation, although anomalies in the benzene profiles for the richer and cooler sooting flames suggest a need for the inclusion of benzene oxidation reactions. THE STRUCTURE OF PARTICLE CLOUD PREMIXED FLAMES Final Report, 14 Sep. 1991 - 13 Sep. 1992
K. Seshadri and A. L. Berlad 13 Sep. 1992 11 p
(Grant NAG3-1297)
(NASA-CR-192827; NAS 1.26:192827) Avail: CASI HC A03/MF A01

The structure of premixed flames propagating in combustible systems containing uniformly distributed volatile fuel particles in an oxidizing gas mixture is analyzed. This analysis is motivated by experiments conducted at NASA Lewis Research Center on the structure of flames propagating in combustible mixtures of lycopodium particles and air. Several interesting modes of flame propagation were observed in these experiments depending on the number density and the initial size of the fuel particle. The experimental results show that steady flame propagation occurs even if the initial equivalence ratio of the combustible mixture based on the gaseous fuel available in the particles, phi sub u, is substantially larger than unity. A model is developed to explain these experimental observations. In the model, it is presumed that the fuel particles vaporize first to yield a gaseous fuel of known chemical composition which then reacts with oxygen in a one-step overall process. The activation energy of the chemical reaction is presumed to be large. The activation energy characterizing the kinetics of vaporization is also presumed to be large. The equations governing the structure of the flame were integrated numerically. It is shown that the interplay of vaporization kinetics and oxidation process can result in steady flame propagation in combustible mixtures where the value of phi sub u is substantially larger than unity. This prediction is in agreement with experimental observations. Author

THE PROPERTIES OF AND ANALYTICAL METHODS FOR DETECTION OF LiOH AND Li2CO3
Guna Selvaduray 8 Feb. 1991 58 p
(Contract NCC2-640)
(NASA-CR-192771; NAS 1.26:192771) Avail: CASI HC A04/MF A01

Lithium hydroxide (LiOH) is used as a CO2 absorbent in the Shuttle Extravehicular Mobility Unit (EMU) Portable Life Support System (PLSS). The first objective was to survey parameters that may be used to indicate conversion of LiOH to Li2CO3, and compile a list of all possible properties, including physical, chemical, structural, and electrical, that may serve to indicate the occurrence of reaction. These properties were compiled for the reactant (LiOH), the intermediate monohydrate compound (LiOH.H2O), and the final product (Li2CO3). The second objective was to survey measurement and analytical techniques which may be used in conjunction with each of the properties identified above, to determine the extent of conversion of LiOH to Li2CO3. Both real-time and post-run techniques were of interest. The techniques were also evaluated in terms of complexity, technology readiness, materials/equipment availability, and cost, where possible. DYNAMIC TEST APPARATUS FOR ELECTRO-RHEOLOGICAL FLUIDS Patent
Wendell C. Maciejewski, inventor (to Navy) 12 Jan. 1993 5 p Filed 16 Sep. 1991
(AD-D015632; US-Patent-5,177,997; US-Patent-Appl-SN-762818) Avail: US Patent and Trademark Office

A device is disclosed for determining the dynamic mechanical properties, specifically, G*, G', G , and Tan Delta, of an electrorheological (ER) fluid as a function of frequency, voltage and temperature. This is accomplished by using the device in conjunction with a suitable driving and environmental control apparatus. An inner tubular electrode, coaxial with an outer tubular electrode, is oscillated along their common longitudinal axis at frequencies in a range of approximately 5 Hz to approximately 1,000 Hz while the spacing between the electrodes is maintained substantially constant at all opposed portions thereof. A power source provides an electrical field encompassing the inner and outer electrodes and the gap therebetween, and the associated driving and environmental control apparatus is operated for measuring the effort required to move the second electrode relative to said first electrode when the ER fluid is received between said inner and outer electrodes. Such measured effort is a function, respectively, of the characteristics of the ER fluid, the rate of oscillation of said second electrode, the strength of the electrical field, and the temperature of the ER fluid. PRODUCTION OF LOW-COST HYDROGEN Quarterly Technical Progress Report No. 11, 1 Apr. - 30 Jun. 1992
1992 7 p
(Contract DE-AC21-89MC-26367)
(DE93-008070; DOE/MC-26367/3235; MTCI-10039-11) Avail: CASI HC A02/MF A01

This eleventh Quarterly Technical Progress Report presents the results of work accomplished during the period 1 Apr. 1992 - 30 Jun. 1992 on production of low-cost hydrogen. The overall objective of this program is to verify the ability of the Manufacturing and Technology Conversion International (MTCI) indirectly heated fluid-bed gasifier to produce a hydrogen-rich product gas from liquefaction by-product streams and from char produced in mild gasification processes. The characterization unit was renovated and another burner/exhaust designed to replace the one that has been in use for several years. Initial shakedown tests for bed calcination indicated that the gasifier should be changed with fresh limestone and kept at temperature, with whatever make-up was required to maintain bed height until calcination was completed as determined by the CO concentration. Char gasification was then initiated and two relatively long-term tests (15.5 and 10.5 hours) were completed at two different temperatures. DOE

STUDIES OF THE ANALYTE-CARRIER INTERFACE IN FLOW INJECTION ANALYSIS Final Report, 1 Jun. 1987 - 31 Jan. 1992
S. D. Brown 1992 35 p
(Contract DE-FG02-86ER-13542)
(DE93-008374; DOE/ER-13542/5) Avail: CASI HC A03/MF A01

Chemical analysis in flowing solution is popular for automation of classical methods. However, most of the classical methods are not specific enough for direct multicomponent analysis of simple mixtures. This research project has the goals of study of rapid multicomponent analysis of transient species in flowing media, and investigations of chemical reactions at interfaces and of effects of competition on distribution of products from interfacial reaction. Work done over the past 4.5 years is summarized; support was terminated. DOE

MECHANISTIC STUDIES OF THE CVD OF SILICON NITRIDE FROM SiF4 AND NH3
R. J. Buss and P. Ho 1992 5 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-004500; SAND-92-2441C; CONF-930571-3) Avail: CASI HC A01/MF A01

An industrial process for the chemical vapor deposition (CVD) of silicon nitride from SiF4 and NH3 was studied with a wide variety of techniques, ranging from numerical models of the coupled chemistry and fluid mechanics to experimental studies of chemical reactions. The latter includes a set of molecular beam experiments that probed the temperature and flux dependencies of the reaction of SiF4 and NH3 at the surface. These experiments showed that the CVD reactor chemistry was dominated by surface kinetics rather than gas-phase decomposition. DOE

FLOW AND MORPHOLOGICAL CONDITIONS ASSOCIATED WITH THE DIRECTIONAL SOLIDIFICATION OF AQUEOUS AMMONIUM CHLORIDE
C. S. Magirl and F. P. Incropera Jan. 1993 229 p
(Contract DE-FG02-87ER-13759)
(DE93-008886; DOE/ER-13759/6) Avail: CASI HC A11/MF A03

Using 27 percent aq. NH4Cl solutions as transparent analog, shadowgraphy and dye injection were used to observe flow and morphology in unidirectional solidification (UDS) from below. Dendritic crystals that form at the cold surface reject lighter, solute-deficient fluid, and instability is shown by finger-type double-diffusive convection. As the mushy two-phase region grows, perturbations at the liquidus interface cause localized remelting and downward development of channels. Solutal plumes emanate from the channels, and in time, double-diffusive convection layers also form in the melt. When the solution is chilled at the sides as well as at the bottom, conditions are influenced by detachment and settling of crystals from the sidewall and by plumes from slanted channels. When a slow, oscillatory rocking motion is imposed on UDS, the freckle-type segregates in the final cast is suppressed. Within the melt, plumes and double-diffusive convection are eliminated. Inertially induced convection mixes the melt and produces a dense slurry. Although channels are eliminated from the bottom mushy region, overall heat transfer and macrosegregation in the cavity are unaffected by the slow rocking. Numerical simulations qualitatively predict trends in the field variables and provide insights on interdendritic flows and macrosegregation (freckle- and A-type segregates), although its quantitative predictions are hampered by simplifying assumptions. DOE

CATALYTIC CONVERSION OF LIGHT ALKANES
J. E. Lyons 30 Sep. 1992 21 p
(Contract DE-FC21-90MC-26029)
(DE93-009646; DOE/MC-26029/3273) Avail: CASI HC A03/MF A01

The third and last quarterly report of 1992 on the Catalytic Conversion of Light Alkanes reviews the work done between July, 1992 and September 30, 1992 on the Cooperative Agreement. The mission of this work is to devise a new catalyst which can be used in a simple economic process to convert the light alkanes in natural gas to oxygenate products which can either be used as clean-burning, high octane liquid fuels, as fuel components or as precursors to liquid hydrocarbon transportation fuel. During the past quarter we have continued to design, prepare, characterize and test novel catalysts for the mild selective reaction of light hydrocarbons with air or oxygen to produce alcohols directly. These catalysts are designed to form active metal oxo (MO) species and to be uniquely active for the homolytic cleavage of the carbon-hydrogen bonds in light alkanes producing intermediates which can form alcohols. We continue to investigate three molecular environments for the active catalytic species that we are trying to generate: electron-deficient macrocycles (PHASE I), polyoxometallates (PHASE II) and framework-substituted zeolites (PHASE III). CONVERSION OF LIGHT HYDROCARBON GASES TO METAL CARBIDES FOR PRODUCTION OF LIQUID FUELS AND CHEMICALS
A. F. Diaz, A. J. Modestino, J. B. Howard, and W. A. Peters Feb. 1993 5 p
(Contract DE-AC22-92PC-92111)
(DE93-009707; DOE/PC-92111/T1; FE-MIT-92111-1) Avail: CASI HC A01/MF A01

Light hydrocarbon gases could be reacted with low cost alkaline earth metal oxide (CaO, MgO) in high-temperature plasma reactor to achieve very high (less than 100 percent) gas conversion to H2, CO, and the corresponding metal carbides. These carbides could be stored, transported, and hydrolyzed to acetylene or methyl acetylene, which in turn could be upgraded to a wide range of chemicals and premium liquid hydrocarbon fuels. An electric arc discharge reactor was built for converting methane. Literature reviews were made. DOE

ACTIVATION OF METHANE BY CLEAN AND CHEMICALLY MODIFIED SINGLE CRYSTAL OXIDE SURFACES Annual Report, Oct. 1991 - Sep. 1992
D. W. Goodman Oct. 1992 37 p
(Contract GRI-5091-260-2182)
(PB93-157295; RF-6888; GRI-92/0486) Avail: CASI HC A03/MF A01

The oxidative coupling of methane to ethane over model MgO catalysts prepared under well-controlled, ultrahigh vacuum conditions was studied using a combination of surface science techniques and reaction kinetic measurements. The utilization of electron energy loss spectroscopy has allowed the characterization of a variety of defects in the catalysts and the identification of the active sites which are responsible for the methane coupling reaction. A quantitative correlation between the density of specific defects and the ethane formation rate indicates that (Li(+1)O(-)) centers are not likely directly involved in the methane activation step as previously proposed. The (Li(+1)O(-)) centers, rather, promote the formation in the near surface region of F-type centers which are responsible for the primary carbon-hydrogen bond scission reaction step. These results suggest new procedures to enhance the active site densities on Li/MgO catalysts and thus offer a potential new approach to enhanced activities and selectivities for this class of materials. A BASIC RESEARCH MODEL OF NATURAL GAS COMBUSTION IN TURBULENT FLOW, PHASE 2 Annual Report, 1 Aug. 1991 - 31 Jul. 1992
Werner J. A. Dahm, Gretar Tryggvason, and Robert Krasny 30 Sep. 1992 83 p
(Contract GRI-5088-260-1692)
(PB93-158509; GRI-92/0421-Phase-2) Avail: CASI HC A05/MF A01

This report describes progress made in the past twelve months in developing a local integral methods (LIM) model for numerically simulating natural gas mixing and combustion in complex flames. The LIM model is fundamentally different from conventional approaches for numerically simulating combustion in turbulent flames. It is based on the experimental observation that the strain-diffusion balance which establishes the mixing and reaction scales in turbulent flames leads to a self-similar internal structure in the diffusion-reaction layers which does not need to be continually recomputed. Instead, these diffusion and reaction scales are represented by a set of self-similar profile shapes whose moments are allowed to evolve freely to satisfy the governing equations. The resulting LIM computations thus need only follow the evolution of material surface in the flow and then solve ODE's (ordinary differential equations) on the surface, rather than PDE's (partial differential equations), throughout the whole flame. Results obtained to date show that the model is capable of correctly

predicting even highly sensitive non-linear characteristics associated with the combustion processes in turbulent natural gas flames, including the local flame extinction phenomenon in large Zeldovich number Arrhenius kinetics. The simplicity of the LIM technique allows large reductions in computation time in comparison with traditional computational approaches, thus allowing far more complex reaction chemistry to be addressed, as well as ranges of Reynolds, Schmidt, and Damkohler numbers which are otherwise completely inaccessible to simulation. ELECTRORHEOLOGICAL FLUIDS: A STRUCTURAL APPROACH TO MECHANISMS Final Report, 1 Aug. 1989 - 31 Jul. 1992
Montgomery T. Shaw 2 Nov. 1992 42 p
(Contract DAAL03-89-G-0080)
(AD-A260563; ARO-27210.4-MS-SM) Avail: CASI HC A03/MF A01

Fibrillation of the particulate phase has been widely observed in electrorheological (ER) fluids and has been suggested as a viable mechanism for the ER phenomena. In this work, the author has investigated the roles of particulate properties such as size and shape anisotropy, dielectric constant and dielectric anisotropy, and conductivity in the structural mechanism of ER fluids. Anhydrous ER fluids based on highly conjugated aromatic polymers were also developed. DTIC

LUMINESCENCE PROBE STUDIES OF IONOMERS. 3: DISTRIBUTION OF DECAY RATE CONSTANTS FOR TRIS BIPYRIDYL RUTHENIUM(2) IN NAFION MEMBRANES Interim Report
Jorge L. Colon and Charles R. Martin 9 Feb. 1993 25 p
(Contract N00014-82-K-0612)
(AD-A260764; TR-80; ONR-TR-80) Avail: CASI HC A03/MF A01

Measurements of the luminescence lifetime of Ru(bpy) sub 3(2+) (bpy = 2,2'-bipyridine) in Nafion were used to probe the heterogeneity of -SO3H(3) sites in the Nafion membrane. The decay kinetics of the probe ion are shown to depart from simple first-order behavior. Alber's model of a continuous distribution of rate constants is used to explain the decay kinetics. The results of these and related investigations indicate that the probe ions reside in sites with different local water activities. DTIC

THE INTERACTION OF HCN/DCN WITH Si(100)-2x1 Technical Report
Y. Bu, L. Ma, and M. C. Lin 1992 33 p
(Contract N00014-89-J-1235)
(AD-A260837; TR-14) Avail: CASI HC A03/MF A01

We have investigated the spectroscopy and reaction of HCN (DCN) adsorbed on Si(100)-2x1 at T(sub s) greater than or equal to 100 K using high resolution electron energy loss spectroscopy (HREELS), X-ray photoelectron spectroscopy (XPS), and ultraviolet photoelectron spectroscopy (UPS). HCN (DCN) formed dimers and/or polymers on the surface at 100 K and higher dosages (D greater than 4 L). The HREEL spectrum obtained after warming a 4.5 L HCN dosed surface to 200 K resembles that obtained with a lower HCN dosage (D less than 0.6 L). Two major species, HCNH and CN, could be identified from this spectrum. The former species showed peaks at 160, 368, and approx. 400 meV for HC=NH, CH, and NH stretching vibrations, respectively, while the latter showed a peak at 263 meV due to the C triple bonds N stretching vibration. In the corresponding DCN experiment, the DC=ND stretching mode was observed at 124 meV. Annealing the sample at 560 K appeared to cause the reorientation of the CN radical from an 'end-on' to a 'side-on' adsorption geometry as evidenced by HREELS, UPS, and XPS analyses. At 600-800 K, the breaking of CH, NH and CN bond occurred on the surface. Above 1000 K, only C and N species remained on the surface following the complete dissociation of CH, NH, and CN bonds and the desorption of H species. DTIC

MECHANISMS OF DECOMPOSITION AND OXIDATION OF BORANE COMPOUNDS
S. H. Bauer 28 Dec. 1992 3 p
(Contract DAAL03-88-K-0187)
(AD-A261137; ARO-25523.2-CH) Avail: CASI HC A01/MF A01

The rates of gas phase reactions between boranes (B2H6, B5H9, B1OH14) and oxygen atoms ((sup 3)P state) were studied (at approximately 350 K) in a flow-tube reactor by determining time dependent levels of OH species, as functions of reactant concentrations. Quantitative fitting of these data for B2H6 and B5H9 led to mechanisms, and estimated rate constants, for the direct attack on the boranes, and for reactions of O((sub 3)P) with fragmentation products (in particular, HBO and HBOH). A degradation sequence was established for each. Measurements (via LIF) of (OH) from B1OH14 were not completed; our data show that under comparable conditions the deca produces approximately 60 fold higher (OH) than does penta. Our QPMS diagnostic of a newly designed flow-tube system and revitalized mass spectrometer permitted evaluation of a rate constant for the net destruction of B5H9, and qualitative estimates of relative concentrations of B5H9 fragmentation products. FLAME-TURBULENCE INTERACTIONS Final Technical Report, 1 Nov. 1989 - 1 Oct. 1992
Domenic A. Santavicca 20 Jan. 1993 116 p
(Grant AF-AFOSR-0025-90)
(AD-A260957; AFOSR-93-0138TR) Avail: CASI HC A06/MF A02

The interaction between individual vortices and a premixed laminar flame was investigated in order to characterize the underlying dynamics of flame-turbulence interactions and thereby gain an improved understanding of premixed turbulent flames. In addition, previous two-dimensional flame structure measurements made in turbulent premixed flames were re-analyzed in order to obtain flame curvature and orientation statistics. DTIC

INTERACTION OF O2 WITH THE Fe(.84)Cr(.16) (001) SURFACE STUDIED BY PHOTOELECTRON SPECTROSCOPY
Jeffrey R. Lince, Stephen V. Didziulis, D. K. Shuh, T. D. Durbin, and J. A. Yarmoff 15 Jul. 1992 41 p
(Contract F04701-88-C-0089)
(AD-A261065; TR-92(2935)-10; SMC-TR-93-02) Avail: CASI HC A03/MF A01

The surface oxidation of a steel-like alloy was investigated to help determine how the efficiency of lubricant additives such as lead naphthenate might be affected by the chemical state of a high-Cr steel bearing surface. Soft X-ray photoelectron spectroscopy (SXPS; hv = 130 - 600 eV) employing synchrotron radiation and X-ray photoelectron spectroscopy (XPS; hv = 1486.6 eV) employing Al-K alpha X rays were used to study the effect of molecular oxygen adsorption (1 to 10(exp 4) L, where 1L triple bonds 10(exp-6) Torr-sec) on the (001) surface of Fe(.84)Cr(.16) at room temperature. The use of multiple photon energies allowed a qualitative determination of the distribution of species in the oxide film perpendicular to the surface. Prior to oxidation, Fe(.84)Cr(.16) samples were annealed to different temperatures to produce varying concentrations of Cr in the top few monolayers of the (001) surface. The differences between the oxide films produced on these different surfaces were determined with SXPS using primarily the Fe 3p, Cr 3p, and valence levels. Small amounts of carbidic carbon (less than or equal to 1 monolayer) that had segregated to the (001) surface of the Fe(.84)Cr(.16) alloy during initial sputter/anneal treatments were removed during the first approx. 5 L 02 exposure. In general, the resistance of the Fe(.84)Cr(.16) (001) surface to oxidation was directly related to the initial Cr concentration at the surface. The oxide films were richer in Cr compared to the bulk concentration for the lowest 02 exposures, and became increasingly enriched in Fe for increasing exposures, in agreement with studies by other groups. The resulting mixed Fe-Cr-O film contained Cr in the form of Cr(3+) for all exposures. DTIC

STRUCTURE OF SODIUM 4-(1'-HEPTYLNONYL) BENZENESULFONATE ADSORBED ON ALUMINA USING H-2 NMR Interim Technical Report
E. Soederlind and Frank D. Blum 28 Feb. 1993 28 p
(Contract N00014-91-J-1274)
(AD-A261224; UMR-FDB-29) Avail: CASI HC A03/MF A01

Deuterium NMR was used to probe the molecular dynamics and structure of the surfactant sodium 4-(1'-heptylnonyl) benzenesulfonate (SHBS) adsorbed from water solution onto alumina. In order to investigate the dynamics of the headgroup, the phenyl ring of the surfactant was specifically deuterated. Two different surface coverages were studied in the temperature range of -30 to 80 C. At the adsorption plateau, evidence for the presence

of two distinct surfactant domains of approximately equal intensities, on the alumina surface, was found. One domain, the inner layer next to the solid surface, gave rise to a quadrupole splitting in the 2H NMR spectrum similar to that found for the surfactant in lamellar liquid crystals; whereas the second domain, the outer layer, gave rise to a broad unsplit resonance indicating a more isotropic environment. The chemical exchange between the two domains was found to be slow on the NMR timescale. At a lower coverage, a broad unsplit resonance appeared in the NMR spectrum showing that the molecular motions are not sufficiently anisotropic to cause any observable quadrupole splittings. With increasing temperature, resonances for both samples were narrowed, and the quadrupole splitting was reduced, reflecting more rapid reorientations of the surfactant molecules. DTIC

TABLES FOR THE THERMOPHYSICAL PROPERTIES OF ETHANE

D. G. Friend, J. F. Ely, and H. Ingham Jan. 1993 319 p See also NISTIR-3953

(PB93-160786; NIST/TN-1346) Avail: CASI HC A14/MF A03

The thermophysical properties of ethane are tabulated for a large range of the fluid state based on recently formulated correlations. For the thermodynamic properties, temperatures from 90 to 625 K at pressures less than 70 MPa are included; for the viscosity, the corresponding range is 90-500 K with pressures to 60 MPa; for the thermal conductivity the range is 90-600 K with pressures to 70 MPa. In addition to the tables of properties, algebraic expressions and associated tables of coefficients are given to allow additional property calculations. Graphical comparisons between experimental property determinations and the correlation are also given both for primary data used in the formulation of the correlations and for additional data. A listing of a FORTRAN program for the evaluation of ethane thermophysical properties is included. NTIS

PHASE-FIELD MODELS FOR ANISOTROPIC INTERFACES

G. B. McFadden, A. A. Wheeler, R. J. Braun, S. R. Coriell, and R. F. Sekerka (Carnegie-Mellon Univ., Pittsburgh, PA.) Feb. 1993 28 p

(PB93-164564; NISTIR-5130) Avail: CASI HC A03/MF A01

The inclusion of anisotropic surface free energy and anisotropic linear interface kinetics in phase-field models is studied for the solidification of a pure material. The formulation is described for a two-dimensional system with a smooth crystal-melt interface and for a surface free energy that varies smoothly with orientation, in which case a quite general dependence of the surface free energy and kinetic coefficient on orientation can be treated; it is assumed that the anisotropy is mild enough that missing orientations do not occur. The method of matched asymptotic expansions is used to recover the appropriate anisotropic form of the Gibbs-Thomson equation in the sharp-interface limit in which the width of the diffuse interface is thin compared to its local radius of curvature. It is found that the surface free energy and the thickness of the diffuse interface have the same anisotropy, whereas the kinetic coefficient has an anisotropy characterized by the product of the interface thickness with the intrinsic mobility of the phase field. DYNAMICS OF GAS-SURFACE INTERACTIONS Final Technical Report, 1 Jun. 1988 - 31 Oct. 1992

Steven J. Sibener 26 Jan. 1993 47 p

(Grant AF-AFOSR-0194-88)

(AD-A261402; AFOSR-93-0038TR) Avail: CASI HC A03/MF A01

This research initiative deals with the interaction of neutral particle, electron, and optical beams with well-characterized single crystal surfaces. These studies are motivated by a desire to understand and control surface reactions, such as surface oxidation, the technological need to characterize the physical properties of thin films and surfaces, and the desire to understand how energy and momentum are exchanged at the surface of a material when it is subjected to gas-surface collisions, electron-surface collisions, optical illumination, or chemical reaction. Experiments aimed at determining the surface phonon dispersion relations for a variety of clean and adsorbate covered systems play a central role in this program. Such measurements are crucial for elucidating how the force constants at e surface differ from those characteristic of the bulk for a given material, and how adsorption of atomic and molecular species modify the force constants, and hence electron density distributions, at and in the vicinity of the surface. The experimental program utilizes two, now fully operational, scattering laboratories that were constructed with significant DoD funding. One of these is a high resolution (energy and momentum) neutral particle scattering apparatus which routinely carries out single phonon inelastic as well as diffractive scattering measurements. The other laboratory houses an inelastic electron scattering instrument which also produces momentum-resolved inelastic scattering data. The capabilities of these two facilities complement each other in many important and useful ways. DTIC

ELECTROCHEMICAL AND SPECTROSCOPIC STUDIES OF MOLTEN HALIDES Final Report, 15 Sep. 1988 - 14 Nov. 1992

Gleb Mamantov 8 Jan. 1993 76 p

(Grant AF-AFOSR-0307-88)

(AD-A261687; AFOSR-93-0101TR) Avail: CASI HC A05/MF A01

This program deals with chemistry and electrochemistry in molten halides, media which are used in the production of several important elements, such as aluminum, magnesium, and fluorine, in some high energy battery systems, as well as in other applications. The emphasis was placed on simple and complex chlorides and fluorides, for example the LiCl-KCl eutectic, the LiF-NaF-KF eutectic (FLINAK), alkali metal and organic tetrachloroaluminates, and cryolite. Pure fluorides usually have high melting points, for example cryolite, Na3AlF6, melts at 1000 C compared to NaAlCl4 which melts at 156 C. The use of molten mixtures of fluorides and chlorides can result in solute chemistry which is quite different from that observed in pure chloride. One complication which cannot be entirely avoided is caused by atmospheric contaminants. Even the parent alkali chloroaluminates contain millimolar quantities of complexed oxide which may result from the interaction of some melts with Pyrex glass. Therefore, studies of solute species at typical electrochemical or spectroscopic concentrations should take into account the presence of oxide species wherever possible. DTIC

VISIBLE LIGHT EMISSION FROM POROUS SILICON EXAMINED BY PHOTOLUMINESCENCE AND RAMAN SPECTROSCOPY

T. R. Guilinger, M. J. Kelly, D. R. Tallant, D. A. Redman, and D. M. Follstaedt 1992 9 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992

(Contract DE-AC04-76DP-00789)

(DE93-006780; SAND-92-1560C; CONF-921101-100) Avail: CASI HC A02/MF A01

We describe the simultaneous acquisition of Raman and photoluminescence (PL) spectra on porous silicon (PS) samples that emit visible light. Spectra were acquired in both ex situ experiments (after exposure to air) as well as in situ experiments (with the PS covered either with the hydrofluoric acid electrolyte used in the formation process or water). In one set of ex situ experiments, we observed an inconsistency in the shift of the wavelength of maximum luminescence intensity for PS samples that exhibit oxygenated character in the Raman spectra. A higher current density produced a red shift in the PL spectra in one experiment, while chemical dissolution of the PS by hydrofluoric acid produced the well-known blue shift in another case. In two in situ experiments, we observed very weak and red-shifted PL for a PS sample immersed in HF (compared to the same sample measured later in air) while in another we immersed air-exposed PS in water and observed a 15-fold increase in PL intensity along with a blue shift in the luminescence maximum. SPECTROSCOPIC EFFECTS OF DISORDER AND VIBRATIONAL LOCALIZATION IN MIXED-HALIDE METAL-HALIDE CHAIN SOLIDS

S. P. Love, B. Scott, L. A. Worl, S. C. Huckett, A. Saxena, X. Z. Huang, A. R. Bishop, and B. I. Swanson 1993 10 p Presented at the International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993

(Contract W-7405-eng-36)

(DE93-007361; LA-UR-93-0004; CONF-930159-11) Avail: CASI HC A02/MF A01

Resonance Raman techniques, together with lattice-dynamics and

Peierls-Hubbard modelling, are used to explore the electronic and vibrational dynamics of the quasi-one-dimensional metal-halogen chain solids (Pt(en)2)(Pt(en)2 X2)(ClO4)4, (en = C2H8N2 and X = Cl, Br), abbreviated 'PLX.' The mixed-halide materials PtCl(1-x)Br(x) and PtCl(1-x)I(x) consist of long mixed chains with heterojunctions between segments of the two constituent materials. Thus, in addition to providing mesoscale modulation of the chain electronic states, they serve as prototypes for elucidating the properties to be expected for macroscopic heterojunctions of these highly nonlinear materials. Once a detailed understanding of the various local vibrational modes occurring in these disordered solids is developed, the electronic structure of the chain segments and junctions can be probed by tuning the Raman excitation through their various electronic resonances. THE SURFACE CHARACTERIZATION OF A SERIES OF HYDROXYBENZENES ON Ag(111): AN EELS AND TDS STUDY Ph.D. Thesis
B. S. Nielsen 27 Jan. 1993 262 p
(Contract W-7405-eng-82)
(DE93-007541; IS-T-1541) Avail: CASI HC A12/MF A03

Interaction of a series of hydroxybenzenes with Ag(111) is investigated by thermal desorption spectroscopy (TDS) and high resolution electron energy loss spectroscopy (EELS). The following were studied: mono-hydroxybenzene; phenol; the o-, m-, and p-dihydroxybenzenes; catechol; resorcinol; hydroquinone; and the 1,2.3-trihydroxybenzene, pyrogallol. Dehydrogenation of the hydroxyl groups upon adsorption is not directly observed in the TDS studies: however, the EELS results suggest possible dehydrogenation. The apparent O-H bond scission is attributed to hydrogen bonding between the surface molecules or to the orientation of the O-H bond aids with respect to the metal surface. Orientations of the mono- and dihydroxybenzene molecules are temperature dependent, whereas that of the trihydroxybenzene may be attributed to the number and position of the hydroxyl substitutents. Phenol and catechol both undergo an inclined-to-perpendicular orientational change. Resorcinol and hydroquinone undergo a perpendicular-to-inclined transformation. Finally, pyrogallol remains inclined at all temperatures until decomposition. DOE

BIMOLECULAR REACTION DYNAMICS FROM PHOTOELECTRON SPECTROSCOPY OF NEGATIVE IONS Ph.D. Thesis
S. E. Bradforth Nov. 1992 422 p
(Contract DE-AC03-76SF-00098)
(DE93-007669; LBL-33328) Avail: CASI HC A18/MF A04

The transition state region of a neutral bimolecular reaction may be experimentally investigated by photoelectron spectroscopy of an appropriate negative ion. The photoelectron spectrum provides information on the spectroscopy and dynamics of the short lived transition state and may be used to develop model potential energy surfaces that are semi-quantitative in this important region. The principles of bound (yields) bound negative ion photoelectron spectroscopy are illustrated by way of an example: a full analysis of the photoelectron bands of CN(-), NCO(-) and NCS(-). Transition state photoelectron spectra are presented for the following systems Br + HI, Cl + HI, F + HI, F + CH3OH, F + C2H5OH, F + OH, and F + H2. A time dependent framework for the simulation and interpretation of the bound (yields) free transition state photoelectron spectra is subsequently developed and applied to the hydrogen transfer reactions Br + HI, F + OH (yields) OP-3, D-1 + HF, and F + H2. The theoretical approach for the simulations is a fully quantum-mechanical wave packet propagation on a collinear model reaction potential surface. The connection between the wavepacket time evolution and the photoelectron spectrum is given by the time autocorrelation function. For the benchmark F + H2 system, comparisons with three-dimensional quantum calculations are made. DOE

ATOMIZATION AND COMBUSTION OF A GELLED, METALLIZED SLURRY FUEL M.S. Thesis
Bruce C. Urbon Dec. 1992 31 p
(AD-A261776) Avail: CASI HC A03/MF A01

Two commercially available atomizers were tested for their ability to atomize a gelled boron slurry fuel. Particle size distributions were measured in non-reacting flow using a Malvern 2600 HSD Laser Diffraction Particle Sizer. A sub-scale ramjet combustor was designed and fabricated which utilized a sudden expansion inlet dump together with inlet air swirl for flame stabilization. An airblast atomizer produced sufficiently small particles for good combustion, but at the cost of a high pressure drop across the atomizer, making it impractical for use in a slurry fueled ramjet. Sustained steady combustion of the slurry fuel was not achieved using the airblast atomizer. A whistle type ultrasonic atomizer also produced sufficiently small particles and at a much lower pressure drop across the atomizer. Sustained stable combustion was achieved using the ultrasonic atomizer which yielded a combustion efficiency of 76 percent at 96 psia and an equivalence ratio of 0.78. DTIC

A MICROMECHANICAL VISCOPLASTIC STRESS-STRAIN MODEL WITH GRAIN BOUNDARY SLIDING
K. P. Walker 28 Feb. 1993 5 p
(Contract DE-AC02-88ER-13895)
(DE93-009109; DOE/ER-13895/3) Avail: CASI HC A01/MF A01

This project was initiated to develop and experimentally verify a self-consistent micromechanics model of polycrystalline Hastelloy-X. A viscoplastic constitutive model was developed for the estimation of the overall mechanical behavior of Hastelloy-X polycrystalline metal from a knowledge of the single crystal behavior. The deformation behavior of the polycrystal was derived from that of single crystals by using a self-consistent method. The single crystal behavior was developed by summing postulated slip on crystallographic slip systems. Plasticity and creep were modeled using a unified viscoplastic model which includes the interaction between these phenomena at elevated temperatures. The validity of the model was directly tested by critical experiments on Hastelloy-X in both the single crystal and polycrystalline versions. DOE

HOT CORROSION OF THE B2 NICKEL ALUMINIDES Final Report
David L. Ellis Mar. 1993 288 p
(Contract NCC3-94; RTOP 505-63-40)
(NASA-CR-191082; E-7621; NAS 1.26:191082) Avail: CASI HC A13/MF A03

The hot corrosion behavior of the B2 nickel aluminides was studied to determine the inherent hot corrosion resistance of the beta nickel aluminides and to develop a mechanism for the hot corrosion of the beta nickel aluminides. The effects of the prior processing of the material, small additions of zirconium, stoichiometry of the materials, and preoxidation of the samples were also examined. Additions of 2, 5, and 15 w/o chromium were used to determine the effect of chromium on the hot corrosion of the beta nickel aluminides and the minimum amount of chromium necessary for good hot corrosion resistance. The results indicate that the beta nickel aluminides have inferior inherent hot corrosion resistance despite their excellent oxidation resistance. Prior processing and zirconium additions had no discernible effect on the hot corrosion resistance of the alloys. Preoxidation extended the incubation period of the alloys only a few hours and was not considered to be an effective means of stopping hot corrosion. Stoichiometry was a major factor in determining the hot corrosion resistance of the alloys with the higher aluminum alloys having a definitely superior hot corrosion resistance. The addition of chromium to the alloys stopped the hot corrosion attack in the alloys tested. From a variety of experimental results, a complex hot corrosion mechanism was proposed. During the early stages of the hot corrosion of these alloys the corrosion is dominated by a local sulphidation/oxidation form of attack. During the intermediate stages of the hot corrosion, the aluminum depletion at the surface leads to a change in the oxidation mechanism from a protective external alumina layer to a mixed nickel-aluminum spinel and nickel oxide that can occur both externally and internally. The material undergoes extensive cracking during the later portions of the hot corrosion. Author

PROCESSING AND PROPERTIES OF Ti5Si3
A. J. Thom, Y. Kim, and M. Akinc 1992 7 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-82)
(DE93-007284; IS-M-743; CONF-921101-82) Avail: CASI HC A02/MF A01

The mechanical properties and oxidation resistance of HIPed Ti5Si3 is measured. HIPing submicron size powder compacts produces a crack-free, fine grain microstructure with significantly higher hardness and toughness than a coarse grain microstructure which contains microcracks within larger grains. Oxidation resistance is also influenced by the grain size. Coarse-grained material has much lower mass gain in an oxidizing atmosphere and exhibits parabolic oxidation kinetics. Fine-grained material shows higher mass gain. The oxidation resistance of fine grained material was measured from 700-1000 C in air. At 700 C, the mass gain at 120 hours is 0.07 mg/sq. cm. At 900 C, cracking of the scale leads to linear oxidation kinetics and significantly higher mass gain. DOE

MECHANICAL PROPERTIES OF MARTENSITIC ALLOY AISI 422
F. H. Huang, W. L. Hu, and M. L. Hamilton (Pacific Northwest Lab., Richland, WA.) Sep. 1992 16 p Presented at the 16th ASTM International Conference on Radiation Effect on Materials, Denver, CO, 22-25 Jun. 1992
(Contract DE-AC06-87RL-10930)
(DE93-006563; WHC-SA-1676; CONF-920673-16) Avail: CASI HC A03/MF A01

HT9 is a martensitic stainless steel that has been considered for structural applications in liquid metal reactors (LMR's) as well as in fusion reactors. AISI 422 is a commercially available martensitic stainless steel that closely resembles HT9, and was studied briefly under the auspices of the US LMR program. Previously unpublished tensile, fracture toughness, and charpy impact data on AISI 422 were reexamined for potential insights into the consequences of the compositional differences between the two alloys, particularly with respect to current questions concerning the origin of the radiation-induced embrittlement observed in HT9. Victoria (Paul Scherrer Inst., Villigen, Switzerland.) 17 Sep. 1992 19 p Presented at the 8th International Conference on Ion Beam Modification of Materials, Heidelberg, Germany, 7-11 Sep. 1992
(Contract W-7405-eng-48)
(DE93-007506; UCRL-JC-111660; CONF-9209200-7) Avail: CASI HC A03/MF A01

Molecular dynamics computer simulations are used to investigate the kinetics of disordering induced by energetic displacement cascades in two ordered intermetallics, Cu3Au and Ni3Al. The mechanisms of defect production in these systems are studied and the results are compared to recent findings in pure metals. Embedded atom potentials are employed which reproduce the main features of the phase diagram, including a disordering transition below the melting point T(sub m) in Cu3Au and an ordered compound up to T(sub m) in Ni3Al. Events with 5 keV recoil energy in crystals containing up to 157,216 atoms at 10 K are simulated. Results of the influence of the displacement cascade on the order parameters are presented and their temporal and spatial evolution are described. Atomic miding in the cascade regions in terms of the atomic mobilities in each sublattice are discussed. The influence of the ordering energy and the melting temperature in the behavior of the compounds is emphasized. DOE

THEORETICAL PREDICTIONS OF PLATINUM-RHODIUM BIMETALLIC CATALYSTS Ph.D. Thesis
A. M. Schoeb 27 Jan. 1993 81 p
(Contract W-7405-eng-82)
(DE93-007540; IS-T-1635) Avail: CASI HC A05/MF A01

After a general introduction to supported bimetallic catalysts and automobile catalytic converters (supports, base metal promoters, noble metals, deterioration of 3-way catalysts, current/future technology), a paper is presented on the topic of surface segregation in bimetallic catalysts. The catalytic properties are influenced by the structure of the cluster surface. Two methods are described to treat this problem: the demanding corrected effective medium (CEM) theory (a non-self-consistent density functional based method); and the simple method of surface modified pair potentials. Predictions are compared with experiment for the heat of formation in Rh(x)Pt(1-x) alloys and for surface segregation in Rh(0.9)Pt(0.1)(111). Results on shape, site composition, and surface micromixing are shown for 201 atom clusters (dispersion of 0.6) and Rh(x)Pt(1-x)(111). The CEM calculated cohesive energy of Rh is slightly smaller than for Pt, but the surface energy of Rh is larger. The driving force for surface segregation is the

relative surface energies, not the relative cohesive energies. One can predict surface energy differences by accounting for the variation of the bond energy with coordination. Recommendations for the development of improved automobile exhaust catalysts are given. The Monte Carlo bimetallic simulation program is described. DOE

INTERNAL STRESSES AND THE CYCLIC DEFORMATION OF AN ALUMINUM MATRIX COMPOSITE Ph.D. Thesis
Birgir Johannesson 1992 221 p
Avail: Univ. Microfilms Order No. BRDX98103

The development of internal stresses in planar random Saffil fiber reinforced with a range of fiber volume fractions was studied theoretically and in monotonic and cyclic deformation (Bauschinger) experiments at room temperature and 77 K. The Eshelby S tensor for a planar random array of fibers is calculated. Because the aluminum/Saffil composites are not isotropic in the transverse directions, the plastic strain used in the calculations has to be determined experimentally. A method for quantifying the anisotropic plastic flow of the aluminum/Saffil composites is proposed and the results are used in calculations of the mean stress hardening rate. The measurements of the thermal stresses obtained in the Bauschinger experiments are in quantitative agreement with results obtained in monotonic tests. The magnitude of the thermal stress at room temperature or 77 K is independent of fiber volume fraction and a comparison with predictions shows that relaxation of the thermal stress increases with fiber volume fraction. Cycling in the Bauschinger experiments reduces the thermal stress and hence the separation of the mean and thermal stresses is essential for a reliable measurement of the mean stress hardening rate. Matrix hardening contributes considerably to the overall hardening of the composite, both at room temperature and 77 K. The modified Orowan-Wilson model, which enables the plastic friction coefficient to be measured in copper-tungsten composites, was applied to the aluminum/Saffil composites. The model requires both the mean stress and the peak stress curves obtained in Bauschinger experiments to be linear in plastic strain. The temperature dependence of the mean stress hardening rate suggests that relaxation is thermally activated. A model for relaxation of the mean stress is proposed. An equation is derived for the number of Orowan loops per fiber and it is assumed that the rate controlling mechanism of relaxation is cross slip of screw dislocations. The estimated activation energy is independent of fiber volume fraction, but the activation volume decreases with increasing fiber volume fraction. Dissert. Abstr.

LASER INITIATED CORROSION PITS ON ALUMINUM Ph.D. Thesis
David Wayne Buzza 1992 191 p
Avail: Univ. Microfilms Order No. DA9305476

A laser initiation technique was developed that could control both the time and the location of pit initiation on a pure aluminum electrode that was immersed in 1.0 M NaCl, pH 11 solution and held under an applied potential. A new technique which was based on the laser initiation technique was invented to initiate an ordered array of pits of up to 61 pits that were spaced 100 micron apart. A study of the shape of single pits by a 3-D post electrolysis SEM method revealed detailed characteristics of pitting corrosion, such as: pit repassivation and secondary pit nucleation within a primary pit. The study also showed that single corrosion pits tended to be round and polished during the early stages of growth (less than 90 s) for applied potential of -0,7 to -0.52 V, SCE, which suggested that a precipitated electropolishing film was present on the pit surface. It was also found that the measured dependency of the current density and the radius of a single pit with time, agreed, for over 3 orders of magnitude of time, with a theoretical model which was based on the pit growth rate being limited by the diffusion controlled dissolution rate of a precipitated aluminum oxychloride film. Other experimental results were found to be inconsistent for a pit growth rate that was limited by the potential drop in solution. Therefore, for these conditions, it was concluded that the pit growth rate was limited by the diffusion controlled dissolution rate of a precipitated aluminum oxychloride film, despite the presence of a vigorous gas evolution reaction. Additional experimental results suggested that a condition for pit repassivation was the disapperance of the precipitated salt film. Once the salt film had disappeared, the pit stability was found to depend on both the (Cl(-)) in the solution adjacent to the pit surface and the applied potential. The pit stability criteria was found to be independent of the pit size. However, large pits were found to be more stable than smaller pits owing to the increased transport resistance for a larger pit. In conclusion, for this system, transport processes were found to be important in determining the pit growth rate and the pit stability. Dissert. Abstr.

HIGH TEMPERATURE FRACTURE TOUGHNESS OF Ni3Al ALLOY IC-396M
D. J. Alexander 1992 7 p The 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting held in Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-008564; CONF-921101-97) Avail: CASI HC A02/MF A01

The fracture toughness of the nickel aluminide alloy IC-396M has been measured from room temperature to 800C. Material was tested in the as-cast condition. Specimens were oriented for crack growth either parallel or perpendicular to the dendritic structure (C-R and R-C orientations, respectively). Both orientations had acceptable levels of toughness from room temperature to 600C. At 650C the toughness decreased markedly with some recovery at 800C. Examination of the fracture surfaces revealed that the fracture mode changed from a ductile tearing mechanism at temperatures up to 600C to interdendritic fracture at 650C and higher temperatures. At 650C the crack grew along the dendrite axis for the C-R specimens, but for the R-C specimens the crack grew out-of-plane in attempting to follow the dendritic structure. It is believed that the presence of the sharp crack in the fracture toughness specimens allowed oxygen to penetrate to the crack tip, where straining exposed metal surfaces that were not protected by an oxide layer. The result was embrittlement of the interdendritic regions and low energy fracture, analogous to intergranular fracture in wrought materials. DOE

ROOM TEMPERATURE FRACTURE OF FeCo
L. Zhao, I. Baker (Dartmouth Coll., Hanover, NH.), and E. P. George 1992 7 p Meeting of the Materials Research Society held in Pittsburgh, PA, 3 Nov. - 4 Dec. 1992
(Contracts DE-AC05-84OR-21400; DE-FG02-87ER-45311; DE-AC05-76OR-00033)
(DE93-008266; CONF-9211127-3) Avail: CASI HC A02/MF A01

FeCo is a B2 intermetallic compound which undergoes an order-disorder transformation. In this paper, the effects of changes in both constitutional and thermal disorder on the room temperature fracture of FeCo are presented. Tensile tests were performed on three compositions of FeCo, Fe30Co70, Fe50Co50, and Fe70Co30. The resulting fracture surfaces were examined by SEM and the grain boundary chemistry was investigated by Auger electron spectroscopy (AES). Ordered Fe50Co50 and Fe70Co30 were very brittle, fracture occurring before yielding, with intergranular fracture occurring in most grains. In contrast, ordered Fe30Co70 showed about 18 percent elongation and exhibited a dimple-type fracture. It was also found that disordering improved the ductility of each composition but had little influence on the fracture mode. AES showed that a low level of sulfur segregation was present at the grain boundaries, suggesting that sulfur segregation alone was not responsible for the brittle behavior of the ordered alloys. DOE

STUDY OF GRAIN REFINEMENT IN Al ALLOY 2519 USING BACKSCATTERING ORIENTATION-CONTRAST MODE IN THE SCANNING ELECTRON MICROSCOPE M.S. Thesis
Jeffrey R. Dunlap Dec. 1992 57 p
(AD-A260886) Avail: CASI HC A04/MF A01

The effects of variations in thermomechanical processing (TMP) parameters on grain refinement in 2519 Al-Cu alloy were studied. Refined grains enhance tensile ductility and are a prerequisite for superplastic response. The TMP variables were adjusted based on particle stimulated nucleation (PSN) theory. Process modifications included increased initial overaging time and decreased subsequent warm rolling temperatures. Backscatter orientation-contrast (BSOC) techniques for the scanning electron microscope (SEM) were developed to achieve grain-orientation contrast. An accelerating voltage of 5 kV resulted in increased intensities for atomic number and orientation contrast. Both grains and theta-phase (Al2Cu) precipitates were revealed on the same micrograph at higher resolutions than attainable in the optical microscope. Quantitative data from micrographs were obtained using image analysis methods. A method based on statistical considerations was developed to determine an approximate critical theta-phase particle diameter (d(sub crit)) for PSN. The theta-phase particle distribution was shown to be an important factor for grain refinement via PSN. DTIC

HIGH STRAIN RATE DAMAGE DEVELOPMENT AND FAILURE MECHANISMS IN TUNGSTEN HEAVY ALLOYS Final Report, 15 Sep. 1988 - 10 Sep. 1992
James Lankford, Jr. 30 Nov. 1992 16 p
(Contract DAAL03-88-K-0204)
(AD-A260856; SWRI-PN-06-2492; ARO-26167.5-MS-A) Avail: CASI HC A03/MF A01

A wide range of tungsten heavy alloy microstructures was subjected to high strain rate tensile and compressive loading. It is found that there exists a critical strain for the onset of unstable shear under compressive loading, which is related to the achievement of a viable mean free path for shear band propagation between tungsten particles. The critical strain thus relates to the W-grains, and not the matrix. Similarly, high strain rate tensile strength and toughness is degraded by the inherently weak W-W interfaces in all current alloys. The key to improvement in this case, will be the achievement of matrix wetting of these surfaces, and thereby ductilizing them. DTIC

HYDROGEN-INDUCED STRESS CORROSION CRACKING SUSCEPTIBILITY ANALYSIS OF PITCH LINKS FROM THE AH-64 APACHE HELICOPTER Final Report
Paul Buckley, Milton Levy, John Beatty, and Richard Brown (Rhode Island Univ., Kingston.) Sep. 1992 19 p
(AD-A260692; MTL/TR-92-69) Avail: CASI HC A03/MF A01

AH-64 Apache helicopter pitch links were evaluated for degradation of mechanical properties due to service and susceptibility to hydrogen embrittlement. The pitch links were manufactured from 4340 electroslag remelted steel and heat treated to an HRC 52 hardness level and/or retempered to a HRC 38 hardness level and vacuum cadmium coated. Samples from fielded pitch links and virgin material were evaluated for comparison of mechanical behavior. Static torque-load tests on pitch links immersed in 3.5 percent NaCl at a potential of -1.2 V(SCE) were conducted for 1000 hours. Stress corrosion cracking resistance under hydrogen embrittlement conditions were determined. Mechanical and stress corrosion testing demonstrated no discernable change in properties due to service. Retempering the HRC 52 pitch links to HRC 38 resulted in properties similar to those expected from the 4340 ESR steel directly heat treated to the same hardness level. The immersion tests indicated no failure of the pitch links even at six times the service torque. The retempered material exhibited greater resistance to hydrogen-induced cracking. DTIC

PREDICTION OF HYDROGEN ENTRY AND PERMEATION IN METALS AND ALLOYS Annual Report, 1 Oct. 1991 - 30 Sep. 1992
Howard W. Pickering Jan. 1993 49 p
(Contract N00014-91-J-1189)
(AD-A260580) Avail: CASI HC A03/MF A01

This report summarizes the past year's results of our continuing experiments into the problem of hydrogen entry and degradation of materials both of planar surfaces and for the more complicated recessed surface. For the planar surface, the hydrogen permeation and scanning tunneling microscopy (STM) techniques are being used, and for the recessed surface, the study uses the hydrogen permeation technique and a microscopy/electrochemical probe technique. In-situ STM of hydrogen adsorption from the gas phase on Si 111(7x7) demonstrates the feasibility of STM for atomic scale study of adsorbed hydrogen. In aqueous solutions, both acidification and chloride ion accumulation within recesses in iron surfaces cause enhanced proton reduction and hydrogen absorption. Flat, smooth surfaces can form or develop recesses as a result of corrosion or other reasons, e.g., grain boundary grooves that form during corrosion of Cr-depleted alloy in sensitized stainless steel. These recesses are found to be just as prone to proton discharge and hydrogen absorption as pre-existing recesses. DTIC

SHEAR BAND FORMATION IN A W-Ni-Fe ALLOY UNDER PLATE IMPACT Technical Report, 1 Nov. 1991 - 31 Oct. 1992
M. Zhou, R. J. Clifton, and A. Needleman Nov. 1992 16 p
(Contract DAAL03-91-G-0025)
(AD-A260702; ARO-28575.1-MS) Avail: CASI HC A03/MF A01

A thin foil of a W-Ni-Fe alloy, 50-200 micrometers in thickness, is sheared for 2 microseconds under plane wave conditions by plate impact. Shear bands observed show more intensely localized deformations than obtained in other experiments. The responses of the constituent phases, the tungsten grains and the matrix, as well as that of the composite alloy over a strain rate range of 10(exp -4)s(exp -1) to 7 x 10(exp 5)s(exp -1) are experimentally obtained and characterized by a viscoplastic model. The effects of strain hardening, thermal softening, material inertia, rate sensitivity, heat conduction and material microscopic inhomogeneity, on dynamic shear localization, are investigated through finite element simulations. Titanium aluminides and titanium alloys are candidate materials for use in hot structure and heat-shield components of hypersonic vehicles because of their good strength-to-weight characteristics at elevated temperature. However, in order to utilize their maximum temperature capability, they must be coated to resist oxidation and to have a high total remittance. Also, surface catalysis for recombination of dissociated species in the aerodynamic boundary layer must be minimized. Very thin chemical vapor deposition (CVD) coatings are attractive candidates for this application because of durability and very light weight. To demonstrate this concept, coatings of boron-silicon and aluminum-boron-silicon compositions were applied to the titanium-aluminides alpha2 (Ti-14Al-21Nb), super-alpha2 (Ti-14Al-23-Nb-2V), and gamma (Ti-33Al-6Nb-1Ta) and to the titanium alloy beta-21S (Ti-15Mo-3Al-3Nb-0.2Si). Coated specimens of each alloy were

subjected to a set of simulated hypersonic vehicle environmental tests to determine their properties of oxidation resistance, surface catalysis, radiative emittance, and thermal shock resistance. Surface catalysis results should be viewed as relative performance only of the several coating-alloy combinations tested under the specific environmental conditions of the LaRC Hypersonic Materials Environmental Test System (HYMETS) arc-plasma-heated hypersonic wind tunnel. Tests were also conducted to evaluate the hydrogen transport properties of the coatings and any effects of the coating processing itself on fatigue life of the base alloys. Results are presented for three types of coatings, which are as follows: (1) a single layer boron silicon coating, (2) a single layer aluminum-boron-silicon coating, and (3) a multilayer coating consisting of an aluminum-boron-silicon sublayer with a boron-silicon outer layer. Ir-Zr ALLOYS AS DIFFUSION BARRIERS BETWEEN Cu AND Si(100)
H. Yang, C. M. Gilmore, and D. E. Ramaker Dec. 1993 11 p
(Contract N00014-91-J-1896)
(AD-A261919; TR-65) Avail: CASI HC A03/MF A01

Ir-Zr alloys were studied as diffusion barriers between Cu and Si with XRD, AES, RBS, and resistivity measurements. An amorphous Ir(0.84)Zr alloy was found to be a better diffusion barrier than a polycrystalline Ir(2.85)Zr alloy, with the amorphous alloy serving as a satisfactory diffusion barrier up to 800 C. The diffusion constants were determined at various temperatures, and the activation energy for Si out-diffusion in Cu/Ir 0.84 Zr/Si was obtained. DTIC

EXTERNAL STRESS-CORROSION CRACKING OF A 1.22-m-DIAMETER TYPE 316 STAINLESS STEEL AIR VALVE
Thomas J. Moore, Jack Telesman, Allan S. Moore, Dereck F. Johnson, and David E. Kuivinen Washington Mar. 1993 21 p Original contains color illustrations
(RTOP 505-62-84)
(NASA-TP-3190; E-6810; NAS 1.60:3190) Avail: CASI HC A03/MF A01; 7 functional color pages

An investigation was conducted to determine the cause of the failure of a massive AISI Type 316 stainless steel valve which controlled combustion air to a jet engine test facility. Several through-the-wall cracks were present near welded joints in the valve skirt. The valve had been in outdoor service for 18 years. Samples were taken in the cracked regions for metallographic and chemical analyses. Insulating material and sources of water mist in the vicinity of the failed valve were analyzed for chlorides. A scanning electron microscope was used to determine whether foreign elements were present in a crack. On the basis of the information generated, the failure was characterized as external stress-corrosion cracking. The cracking resulted from a combination of residual tensile stress from welding and the presence of aqueous chlorides. Recommended countermeasures are included. Author

AQUEOUS CLEANING OF FLUX RESIDUE FROM SOLDER JOINTS Final Report
Carol M. Krska, Don Bowlen, John Houtz, Roger Koelling, Wayne McLarren, and Bill Rowe Aug. 1992 26 p
(Contract DE-AC04-76DP-00613)
(KCP-613-4803) Avail: CASI HC A03/MF A01

Solder joints have traditionally been cleaned using chlorinated or fluorinated solvents. Alternate processing is addressed. One process involved using a saponifier/water solution to remove rosin flux residues; the other process involved using a water-soluble flux and water to remove the residues. Although both processes were satisfactory, the water-soluble flux with water cleaning proved to be the best. Author (revised)

DEFORMATION MECHANISMS OF NiAl CYCLICLY DEFORMED NEAR THE BRITTLE-TO-DUCTILE TRANSITION TEMPERATURE Final Report
Cheryl L. Cullers (Georgia Inst. of Tech., Atlanta.) and Stephen D. Antolovich (Georgia Inst. of Tech., Atlanta.) Apr. 1993 105 p
(Contract NCC3-295; RTOP 505-63-5A)
(NASA-CR-191121; E-7745; NAS 1.26:191121) Avail: CASI HC A06/MF A02

The intermetallic compound NiAl is one of many advanced materials which is being scrutinized for possible use in high temperature, structural applications. Stoichiometric NiAl has a high melting temperature, excellent oxidation resistance, and good thermal conductivity. Past research has concentrated on improving monotonic properties. The encouraging results obtained on binary and micro-alloyed NiAl over the past ten years have led to the broadening of NiAl experimental programs. The purpose of this research project was to determine the low cycle fatigue properties and dislocation mechanisms of stoichiometric NiAl at temperatures near the monotonic brittle-to-ductile transition. The fatigue properties were found to change only slightly in the temperature range of 600 to 700 K; a temperature range over which monotonic ductility and fracture strength increase markedly. The shape of the cyclic hardening curves coincided with the changes observed in the dislocation structures. The evolution of dislocation structures did not appear to change with temperature. Author

MECHANICAL ALLOYING PROCESSING AND APPLICATION TO DEVELOPMENT OF STRUCTURAL MATERIALS Final Report, 1 Jun. 1991 - 15 Aug. 1992
Thomas H. Courtney 21 Sep. 1992 8 p
(Contract DAAL03-91-G-0092)
(AD-A261251; UVA/525272/MSE93/101; ARO-28639.2-MS) Avail: CASI HC A02/MF A01

This report summarizes results of several areas of research dealing with mechanical alloying of materials having potential structural use. The areas involve modeling of the process, synthesis of unique materials via mechanical alloying and consolidation of mechanically alloyed products. The latter area is one receiving most current attention as consolidation involves high temperatures and (usually) pressures. This can lead to a 'loss' of the unique structures produced by mechanical alloying. Thus, consolidation studies attempt to produce fully dense material maintaining many of the desirable properties manifested by mechanically alloyed powders. DTIC

FATIGUE IN SINGLE CRYSTAL NICKEL SUPERALLOYS Technical Progress Report
Daniel P. DeLuca 16 Feb. 1993 6 p
(Contract N00014-91-C-0124)
(AD-A261742; FR21998-16) Avail: CASI HC A02/MF A01

This program investigates the seemingly unusual behavior of single crystal airfoil materials. The fatigue initiation processes in single crystal (SC) materials are significantly more complicated and involved than fatigue initiation and subsequent behavior of a (single) macrocrack in conventional, isotropic, materials. To understand these differences is the major goal of this project. DTIC

SOLIDIFICATION PROCESSING AND PHASE TRANSFORMATIONS IN ORDERED HIGH TEMPERATURE ALLOYS Final Report, 30 Mar. 1990 - 30 Sep. 1992
William J. Boettinger, Leonid A. Bendersky, and Ursula R. Kattner 20 Jan. 1993 205 p

(DARPA Order 7469)
(AD-A261751) Avail: CASI HC A10/MF A03

Useful high temperature alloys generally have microstructures consisting of more than one phase. Multiphase microstructures are necessary to develop acceptable toughness and creep strength in high temperature intermetallic alloy matrices. The optimum microstructures must be developed by a careful selection of processing path that includes both solidification and solid state heat treatment. Research has been conducted on the rapid solidification of selected intermetallic alloys and on the phase transformation paths that occur during cooling, primarily in the Ti-Al-Nb system. This report describes research performed in the Metallurgy Division at NIST under DARPA order 7469 between 1/1/89 and 12/31/92. Various research tasks were completed and the results have been published or have been submitted for publication. DTIC

FUNDAMENTAL ASPECTS OF METAL JOINING: THE STUDY OF STRONG INTERFACES Final Report
Anthony T. Paxton and Mark VanSchilfgaarde Dec. 1992 31 p
(Contract N00014-92-J-0006)
(AD-A261293) Avail: CASI HC A03/MF A01

Our aim for 1992 was to investigate whether modern quantum mechanical methods can be useful in the study of interfaces between dissimilar materials, and to complete at least a modest piece of work to demonstrate feasibility. This has been achieved. We developed an approximate quantum mechanical approach to the problem of dissimilar transition-metal interfaces. Because of its approximate nature, we have devoted a large effort to testing the scheme against experiment and first-principles theory. Our expertise in local density functional theory has allowed us to draw upon our first-principles capability both in determining parameters for our model Hamiltonian and in testing it. We have studied in some detail a lattice-mismatched interface between pure molybdenum and rhenium metals. Our conclusions concerning this system are that the shear strength of the interface is diminished from the theoretical strength by a factor of about twenty; the reduction is due to the presence of a misfit dislocation that glides in the interface during deformation. POSITION SENSITIVE ATOM PROBE STUDY OF THE DECOMPOSITION OF A Cu-2.6 AT. PERCENT Co ALLOY
R. P. Setna (Oxford Univ., England.), J. M. Hyde (Oxford Univ., England.), A. Cerezo (Oxford Univ., England.), G. D. W. Smith (Oxford Univ., England.), and M. F. Chisholm Dec. 1992 23 p Presented at the 39th International Field Emission Symposium, Halifax, Nova Scotia, 9-14 Aug. 1992
(Contract DE-AC05-84OR-21400)
(DE93-006737; CONF-9208205-1) Avail: CASI HC A03/MF A01

This paper presents a Position Sensitive Atom Probe study of phase decomposition in a Cu-2.6 at. % Co alloy, aged at 723 K for various times up to 24 hours. The composition and ageing temperature of the alloy were chosen such that the free energy barrier to decomposition was small. Statistical techniques are used to characterize the fine-scale microstructures present in the early stages of phase separation and three-dimensional atomic reconstructions of the alloys are presented. The experimental results from the Position Sensitive Atom Probe are compared with Monte Carlo simulations and with the sub-regular solution-classical nucleation model to gain a greater insight into the nature of the processes taking place in the early stages of phase decomposition. Results demonstrate a complex range of behavior, from the development of enriched and partially diffuse regions of Co to the formation of Co-rich (alpha) precipitates. Monte Carlo simulations adequately mimic many of the features observed in the experimental data. DOE

DEVELOPMENT OF DISPERSION-STRENGTHENED XD (TRADEMARK) Cu ALLOYS FOR HIGH HEAT-FLUX APPLICATIONS
K. Sharvan Kumar Apr. 1993 44 p Original contains color illustrations
(Contract NAS3-26474; RTOP 584-03-11)
(NASA-CR-191124; E-7701; NAS 1.26:191124) Avail: CASI HC A03/MF A01; 4 functional color pages

In a previous effort sponsored by NASA LeRC, the XD(trademark) process was used to produce ZrB2 particulate reinforcements in Cu and the resulting extruded material was microstructurally characterized and evaluated in tension over a range of temperatures. A problem that was encountered in that study was microstructural inhomogeneity resulting from the frequent presence of 'ZrB2 agglomerates' that were several microns in size. The presence of these agglomerates was attributed to improper mixing of powders in the green compact used in the XD process for elemental boron powder segregation. In this program, several milling parameters were examined in an effort to optimize this processing step; two levels of ZrB2 reinforcements were considered (7 vol. percent and 15 vol. percent). Microstructures of the reacted powder mass were examined to verify the absence of these agglomerates. Larger bathes of powder were then mixed, reacted, machined to size, canned, and extruded. The microstructure and tensile properties of these extrusions were examined, and the measured properties were correlated with the observed microstructure. Large unreacted or partially reacted Zr particles were present. These particles affected the mechanical properties deleteriously, and their presence is attributed to insufficient heat of reaction during XD synthesis. Alternate processing routes are recommended. (DE93-006763; SAND-92-1596C; CONF-921101-91) Avail: CASI HC A01/MF A01

Metal colloids in glasses can yield an enhanced chi(sup 3) susceptibility which leads to an intensity dependent refractive index. Ion implantation is a convenient means of introducing the metal species. The host glass plays an important role in colloid formation. Ag-colloid formation was characterized in various silicate glasses and, in addition, the formation of colloids in Ag-doped phosphate glass as a function of N and H implantation were studied. Some preliminary results for Cu-implanted glasses are presented. DOE

AN INVESTIGATION OF THE DEGRADATION OF FLUORINATED ETHYLENE PROPYLENE (FEP) COPOLYMER THERMAL BLANKETING MATERIALS ABOARD LDEF IN THE LABORATORY
A. E. Stiegman, David E. Brinza, Mark S. Anderson, Timothy K. Minton, Eric G. Laue, and Ranty H. Liang 15 May 1991 25 p
(Contract NAS7-918)
(NASA-CR-192824; NAS 1.26:192824; JPL-Publ-91-10) Avail: CASI HC A03/MF A01

Samples of fluorinated ethylene propylene copolymer thermal blanketing material, recovered from the Long Duration Exposure Facility (LDEF), were investigated to determine the nature and the extent of degradation due to exposure to the low-Earth-orbit environment. Samples recovered from the ram-facing direction of LDEF, which received vacuum-ultraviolet (VUV) radiation and atomic-oxygen impingement, and samples from the trailing edge, which received almost exclusively VUV exposure, were investigated by scanning electron microscopy and atomic force microscopy. The most significant result of this investigation was found on samples that received

only VUV exposure. These samples possessed a hard, embrittled surface layer that was absent from the atomic-oxygen exposed sample and from unexposed control samples. This surface layer is believed to be responsible for the 'synergistic' effect between VUV and atomic oxygen. Overall, the investigation revealed dramatically different morphologies for the two samples. The sample receiving both atomic-oxygen and VUV exposure was deeply eroded and had a characteristic 'rolling' surface morphology, while the sample that received only VUV exposure showed mild erosion and a surface morphology characterized by sharp high-frequency peaks. The morphologies observed in the LDEF samples, including the embrittled surface layer, were successfully duplicated in the laboratory. Author

DETERMINATION OF THE THERMAL STABILITY OF PERFLUOROPOLYALKYL ETHERS BY TENSIMETRY

Larry A. Helmick (Cedarville Coll., OH.) and William R. Jones, Jr. May 1992 32 p Presented at the Society of Tribologists and Lubrication Engineers Annual Meeting, Philadelphia, PA, 4-7 May 1992; sponsored by the Society of Tribologists and Lubrication Engineers

(RTOP 505-53-1A)

(NASA-TM-106081; E-7699; NAS 1.15:106081) Avail: CASI HC A01/MF A01

The thermal decomposition temperatures of several perfluoropolyalkyl ether fluids were determined with a computerized tensimeter. In general, the decomposition temperatures of the commercial fluids were all similar and significantly higher than those for noncommercial fluids. Correlation of the decomposition temperatures with the molecular structures of the primary components of the commercial fluids revealed that the stability of the fluids was not affected by carbon chain length, branching, or adjacent difluoroformal groups. Instead, stability was limited by the presence of small quantities of thermally unstable material and/or chlorine-containing material arising from the use of chlorine containing solvents during synthesis. Finally, correlation of decomposition temperatures with molecular weights for two fluids supports a chain cleavage reaction mechanism for one and an unzipping reaction mechanism for the other. DEVELOPMENT OF ASTM STANDARDS IN SUPPORT OF ADVANCED CERAMICS DEVELOPMENT

C. R. Brinkman, G. D. Quinn (National Inst. of Standards and Technology, Gaithersburg, MD.), and R. W. McClung 1993 28 p Presented at the 38th ASME International Gas Turbine and Aeroengine Congress and Exhibition, Cincinnati, OH, 24-27 May 1993

(Contract DE-AC05-84OR-21400)

(DE93-003024; CONF-930502-1) Avail: CASI HC A03/MF A01

The ASTM Committee C-28 on Advanced Ceramics was organized in 1986 when it became apparent that ceramics were being considered for extensive use in such applications as heat engines in the automotive and aerospace industries. It was determined that these standards should be written for the production, inspection, testing, data analysis, reliability, and probabilistic design for utilization of advanced ceramics. Advanced ceramics include both monolithic and composite materials. The ASTM Committee C-28 is organized into five subcommittees as follows: properties and performance, design and evaluation, characterization and processing, ceramic composites, and nomenclature. A summary overview is given of work performed to date and ongoing efforts in developing standards by these various subcommittees. DOE

STRUCTURE AND PROPERTIES OF a-C: N FILNS PREPARED BY PULSED EXCIMER LASER DEPOSITION

Fulin Xiong, R. P. H. Chang (Northwestern Univ., Evanston, IL.), and C. W. White 1992 6 p The 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Meeting held in Boston, MA, 30 Nov. - 5 Dec. 1992

(Contracts DE-AC05-84OR-21400; DE-FG02-87ER-45314)

(DE93-007908; CONF-921101-94) Avail: CASI HC A02/MF A01

We present results on the synthesis of a-C:N films deposited by pulsed excimer laser ablation of graphite in a nitrogen gas ambient. Analysis with RBS and forward recoil spectrometry show that the films are hydrogen-free and nitrogen can be incorporated up to 40 percent by varying the nitrogen gas pressure. Electron microscopy has identified these films to be amorphous. Raman spectroscopy, infrared spectroscopy, and electron energy loss spectroscopy have revealed carbon-nitrogen bonding structures. Compared to a-diamond films prepared by the same technique, the C:N films still possess the properties of high mechanical hardness, chemically inertness, and good wear resistance, but incorporation of nitrogen into the films generally degrades their diamond-like properties. Results suggest that nitrogen doping effect is presented in the films under the present process, instead of carbon-nitrogen compound formation. DOE

THE NATURE OF THE GLASS TRANSITION AND ITS DETERMINATION BY THERMAL ANALYSIS

B. Wunderlich (Tennessee Univ., Knoxville.) 1993 15 p Presented at the American Society of Testing and Materials (ASTM) Meeting on Glass Transition, Atlanta, GA, 4-5 Mar. 1993

(Contract DE-AC05-84OR-21400)

(DE93-006746; CONF-930398-1) Avail: CASI HC A03/MF A01

In this paper operational definitions of the glass transition and the pertinent condensed phases are given. This is followed by a description of the basic observations of glass transitions via thermal analysis using calorimetry, dilatometry, as well as thermomechanical, dielectric, and dynamic mechanical analysis. The time dependence of the glass transition causes hysteresis phenomena and physical ageing. Strain effects on the observation of the glass transition are identified. Complications resulting in symmetric and asymmetric broadening of the glass transition are linked to nanometer and micrometer scale phase separations. Finally, a rigid amorphous phase is identified in some semicrystalline polymers. DOE

SPUTTER DEPOSITION OF YTTRIUM-OXIDES

A. F. Jankowski, L. R. Schrawyer, and J. P. Hayes Nov. 1992 22 p Presented at the 39th National Symposium of the American Vacuum Society, Chicago, IL, 9-13 Nov. 1992

(Contract W-7405-eng-48)

(DE93-007499; UCRL-JC-110346; CONF-921129-7) Avail: CASI HC A03/MF A01

The yttrium-oxide phase diagram contains only one equilibrium compound, a Y2O3 cubic structure. The process of reactive sputter deposition is used to synthesize previously unreported, yttrium rich oxide compounds. A planar magnetron is operated in the dc mode using a working gas mixture of argon-20 percent oxygen. For low sputter gas pressure and flow conditions, the yttrium content of the coating is directly controlled as a function of the applied target power, i.e., the deposition rate. The composition and structure of the coatings are characterized using Auger depth profiling and x-ray diffraction. A continuous series of compounds are formed with an orthorhombic crystal structure for concentrations ranging from 40 to 75 at. percent yttrium. DOE

CORRELATION OF DAMAGE THRESHOLD AND SURFACE GEOMETRY OF NODULAR DEFECTS IN HR COATINGS AS DETERMINED BY IN-SITU ATOMIC FORCE MICROSCOPY

M. C. Staggs, M. R. Kozlowski, W. J. Siekhaus, and M. Balooch Oct. 1992 10 p Presented at the SPIE Symposium on Boulder Damage, Boulder, CO, 28-30 Oct. 1992

(Contract W-7405-eng-48)

(DE93-007509; UCRL-JC-111464; CONF-9210295-1) Avail: CASI HC A02/MF A01

Atomic force microscopy (AFM) was used to determine in-situ the correlation between the surface dimensions of defects in dielectric multilayer optical coatings and their susceptibility to damage by pulsed laser illumination. The primary surface defects studied were micron-scale domes associated with the classic nodule defect. The optical film studied was a highly reflective dielectric multilayer consisting of pairs of alternating HfO2 and SiO2 layers of quarter wave thickness at 1.06 microns. Nodule defect height and width dimensions were measured prior to laser illumination on two different samples. Correlation between these dimensions supported a simple model for the defect geometry. Defects with high nodule heights (greater than 0.6 micron) were found to be most susceptible to laser damage over a range of fluences between 0 - 35 J/sq cm (1.06 microns, 10 ns, and 1/e(exp 2) diameter of 1.3 mm). Crater defects, formed by nodules ejected from the coating prior to illumination, were also studied. None of the crater defects were damaged when they were illuminated in the same range of fluences as the nodule defects. DOE

TEMPERATURE DEPENDENT SENSOR RESPONSE CAUSED BY POLYMER-SOLVENT INTERACTIONS
M. A. Butler 1992 7 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-005368; SAND-92-2378C; CONF-930571-4) Avail: CASI HC A02/MF A01

Absorption of organic solvents by a range of polymers has been used as the chemical transduction mechanism for a variety of sensors. This paper examines the effect of the polymer-solvent interaction on the temperature dependence of the sensor response. Optical interferometric cavities are formed on the end of an optical fiber by plasma-deposition of a fluorocarbon polymer. Swelling of the polymer when exposed to various solvent vapors produces changes in the reflectivity of the fiber tip. The temperature dependence of the sensor response is related to the strength of the polymer-solvent interaction and the heat of vaporization of the solvent. DOE

CHROMATE-FREE CORROSION RESISTANT TALC COATINGS FOR ALUMINUM ALLOYS
R. G. Buchheit and G. E. Stoner (Virginia Univ., Charlottesville.) 1992 3 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-005370; SAND-92-2396C; CONF-930571-5) Avail: CASI HC A01/MF A01

Passivity developed by immersion in an alkaline Li salt solution is retained when the Al surface is exposed to an aggressive solution like aerated NaCl. A process for coating Al was developed using a method similar to the chromate conversion process. This process imparts appreciable corrosion resistance, but does not use or produce hazardous chemicals. Coatings are formed by immersion in 0.1 M Li carbonate solution whose pH is adjusted to 11.5-12.0 by LiOH additions. Immersion times of 1.5 to 90 min were used to produce talc coatings; up to this point, the best time has been 15 min. Increased corrosion resistance is obtained if the coating is sealed by elevated temperature treatment in air or distilled water. DOE

A MODEL FOR THE FILLING OF COLD CAVITIES WITH SOLIDIFYING, SEMI-CRYSTALLINE POLYMERS
T. D. Papathanasiou (Imperial Coll. of Science and Technology, London, England.) and D. C. Guell 1992 17 p Presented at the ANTEC 1993 Society of Plastics Engineers Meeting, New Orleans, LA, 9-13 May 1993
(Contract W-7405-eng-36)
(DE93-003817; LA-UR-92-3668; CONF-930584-1) Avail: CASI HC A03/MF A01

A model for the filling stage of injection molding that includes wall solidification and crystallization was used to investigate the interaction between solidification and pressure drop during the filling of a rectangular plate with high-density polyethylene. We find that wall solidification affects the pressure drop in a complex way, reflecting the interplay between reduction in the area available for flow and thermal insulation of the still-molten polymer. Development of crystallinity on the surface of the part is also modelled under conditions of uniform and spatially varying cooling. Results indicate that nonuniform cooling can result in complex crystallinity distributions which are determined by thermal history of solidified polymer, duration of filling stage and by exact dependence of crystallization kinetics on temperature. DOE

NMR STUDIES OF ION MOBILITY AND ASSOCIATION IN POLYETHER-BASED POLYMER ELECTROLYTES Technical Report, Apr. 1992
Steven G. Greenbaum 25 Jan. 1993 69 p
(Contract N00014-92-J-1629)
(AD-A260662; TR-1) Avail: CASI HC A04/MF A01

The results of several investigations of polyether-based polymer electrolytes by nuclear magnetic resonance (NMR) spectroscopy conducted in the author's laboratory and by other groups are reviewed. For both Li-7 and Na-23 NMR, the onset of motional line-narrowing occurs at about the glass transition, illustrating the importance of polymer segmental motion to ion transport. Examples of the ability of NMR to probe cation-anion interactions are discussed. These include chemical shift variations corresponding to different Li(+) environments and nuclear quadrupole coupling and relaxation behavior as a probe of Na(+) environment. DTIC

MACROMOLECULES FOR INHIBITION OF CORROSION AND WEAR Progress Report
Alfeo A. Conte, Jr. and Vinod S. Agarwala 14 Dec. 1992 30 p
(AD-A261041; NAWCADWAR-92112-60) Avail: CASI HC A03/MF A01

The phthalocyanines and Schiff base compounds are uniquely qualified inhibitors for corrosion. They are high electron density molecules for interaction with the metal surface, and possess large spatially arranged structures to serve as environmental barriers. Additionally, these compounds do stack-up as layered structures which provides shear planes, thus serving as lubricants. A number of these compounds have been synthesized and studied. Both electrochemical impedance spectroscopic and potentiostatic polarization techniques were used to determine their corrosion inhibition efficiencies. Wear studies were made using grease lubricated stainless steel miniature bearings. The results have shown that Schiff base compounds can be good additives for greases as they enhance wear life of bearings and inhibit corrosion by at least and order of magnitude. Although phthalocyanines, both monomers and polymers, provided a significant corrosion inhibition efficiencies (greater than 90 percent), they were not effective lubricants compared to the Schiff bases. IN SITU SURFACE STUDIES OF CONVERSION COATINGS FOR STEEL AND ALUMINUM Final Report, 15 Apr. 1989 - 14 Sep. 1992
Henry W. White, Florian Mansfeld, and Paul Bryant 10 Nov. 1992 27 p
(Contract DAAL03-89-K-0084)
(AD-A261016; ARO-26400.7-MS) Avail: CASI HC A03/MF A01

The primary goals of the work were to develop mechanisms of corrosion protection for cerium based surface layers on aluminum alloys and on polyacrylic acid (PAA) complexed zinc phosphate conversion coatings on steel. Atomic force. microscopy (AFM) using tunnel current control was developed and applied to several problems. The cerium based coatings on

Al 6061-T6 are shown to consist of two principle components--a poorly ordered monohydrated aluminum oxide, and an insoluble cerium oxide which forms at areas concentrated with impurities and alloying elements. Electrochemical action during the surface modification process fosters the precipitation of cerium compounds which inhibit further attack. The addition of high molecular weight PAA to the phosphating bath can significantly improve both resistance to corrosion and top-coat adherence of zinc phosphate conversion coatings on steel. Raman spectra showed the compositions of both unmodified and PAA modified films to be zinc phosphate dihydrate. Single crystallite surfaces were imaged using AFM. The morphologies of the unmodified and modified films were in general quite similar, but subtle differences were apparent. Several other projects involving surface layers and adsorbates were carried out and are described. DTIC

The overall objective of the program was to develop and test a surface cleaning/preparation and corrosion resistant protective polymer coating for the interior of the AEDC Environment Test Facility ferrous metal air supply ducts. The types of cleaning techniques acceptable to the AEDC were basically limited to chemical approaches. Typically, sand or abrasive blasting is used to produce corrosion-free, clean surfaces for coating steel substrates. These particular techniques are strongly discouraged and basically outlawed at the AEDC facilities. Water blasting is an acceptable technique, but requires a high pressure water stream, expensive equipment, and considerable clean up. DTIC

A process for bonding elastomeric material to a metal part includes coating a heat curable adhesive on the surfaces of the metal part to be bonded. The metal part is placed in a mold, a bottom plate and an upper transfer pot of a transfer molding machine is preheated to a predetermined cure temperature. A predetermined quantity of uncured elastomeric material is loaded into the transfer pot. The mold containing the adhesive coated metal part is clamped to the bottom plate, and almost contemporaneously, the uncured elastomeric material is pressed into the mold while maintaining heat and pressure in the mold for a time sufficient to vulcanize and thereby cure the elastomeric material simultaneously with the adhesive, whereby contacting surfaces of the metal part are strongly bonded to the vulcanized elastomeric material.

The semicrystalline polyimide prepared by reaction of 3,3',4,4' benzophenonetetracarboxylic (BTDA) and 1,3-bis(4-aminophenoxy 4' benzoyl) benzene (1,3-BABB) is modified so that it can be more readily processed to form adhesive bonds, moldings, and composites. The stoichiometric ratio of the two monomers, BTDA and 1,3-BABB is controlled so that the intermediate polyamide acid is of a calculated molecular weight. A polyimide acid with excess anhydride groups is then reacted with the stoichiometrically required amount of monofunctional aromatic or aliphatic amine required for complete endcapping. The stoichiometrically offset, encapped polyimide is processed at lower temperatures and pressures than the unmodified high molecular weight polyimide with the same repeat unit, and exhibits an improved melt stability.

In the present invention, linear aromatic polyimides containing the cyclobutene-3,4-dione moiety were produced from the reaction of a substituted or unsubstituted 1,2-bis(4-aminoanilino) cyclobutene-3,4-dione (SQDA) with various aromatic dianhydrides. These polymers had high molecular weights and their glass transition temperatures (Tgs) were greater than 500 C. Despite the very high Tg, these polymers exhibited excellent adhesion to glass. In addition, the films of these polyimides increased in flexibility with increasing cure temperatures. The novelty of this invention lies in the linear aromatic polyimide containing the cyclobutene-3,4-dione moiety. The presence of this moiety causes such changes in properties as Tgs greater than 500 C, excellent adhesion to glass, and increased flexibility with increasing cure temperatures.

NEW DIRECTIONS IN PHTHALOCYANINE PIGMENTS Final Report
Michael R. VanDeMark 9 Aug. 1992 44 p
(Contract NAS8-38259)
(NASA-CR-192443; NAS 1.26:192443) Avail: CASI HC A03/MF A01

The objectives were the following: (1) investigation of the synthesis of new phthalocyanines; (2) characterization of the new phthalocyanines synthesized; (3) investigate the properties of the newly synthesized phthalocyanines with emphasis on UV protection of plastics and coatings; and (4) utilize quantum mechanics to evaluate the structural relationships with possible properties and synthetic approaches. The proposed research targeted the synthesis of phthalocyanines containing an aromatic bridge between two phthalocyanine rings. The goal was to synthesize pigments which would protect plastics when exposed to the photodegradation effects of the sun in space. The stability and extended conjugation of the phthalocyanines offer a unique opportunity for energy absorption and numerous radiative and non-radiative energy loss mechanisms. Although the original targeted phthalocyanines were changed early in the project, several new and unique phthalocyanine compounds were prepared. The basic goals of this work were met and some unique and unexpected outcomes of the work were the result of the integral use of quantum mechanics and molecular modeling with the synthetic effort. INORGANIC AND BIOLOGICAL ELECTRON TRANSFER ACROSS AN ELECTRONICALLY CONDUCTIVE COMPOSITE POLYMER MEMBRANE Interim Report
Del R. Lawson, Wenbin Liang, and Charles R. Martin 22 Feb. 1993 15 p
(Contract N00014-82-K-0612)
(AD-A261642; ONR-TR-81) Avail: CASI HC A03/MF A01

We describe in this paper an experiment involving an electronically conductive polymer that, to our knowledge, has not been described

previously. A free-standing conductive polymer (polypyrrole)-based membrane separates a solution of an electron donor from a solution of an electron acceptor. Because the conductive polymer is both electronically and anionically conductive, the membrane can transport electrons from the donor solution to the acceptor solution, and anions in the opposite direction, such that a sustainable electron-transfer reaction is driven across the conductive polymer membrane. We demonstrate such transmembrane electron/ion-transfer processes using both an inorganic and a biochemical electron donor/acceptor system. The biochemical case is of particular interest because we show that the reduced form of the enzyme glucose oxidase can give its electrons directly to the polypyrrolemembrane surface. Direct electron transfer is usually not possible at inorganic metals. DTIC

CHARACTERIZATION OF THE SYNTHESIS OF M-61, A RANDOM EQUILIBRIUM SILICONE TERPOLYMER, USING DRY STARTING MATERIALS Final Report

J. W. Schneider, G. K. Baker, T. J. Reno, R. S. Sanders, and J. J. Wyckoff Dec. 1992 50 p

(Contract DE-AC04-76DP-00613)

(KCP-613-4985) Avail: CASI HC A03/MF A01

Process characterization of the synthesis of M-61, a random equilibrium silicon terpolymer, using 'dry' starting materials has been completed. Tests indicate considerable moisture is present in the starting materials: octamethyl cyclotetra siloxane, octaphenyl cyclotetra siloxane, tetramethyl cyclotetra siloxane, octaphenyl cyclotetra siloxane, tetramethyl tetravinyl cyclotetra siloxane, and a trimethyl endblocker. The presence of moisture provides -OH endblocking of the polymer chain and renders the trimethyl endblocker used to control the weight average molecular weight ineffective. The liquid starting materials were dried with molecular sieves while the octaphenyl cyclotetra siloxane powder was dried in an oven prior to use. Author

The research is in the area of chemical reactions on surfaces and is concerned with molecules and solids that model systems of technological and environmental significance. In particular, we study heteroatom organic adsorbates containing halogens, sulfur, oxygen, phosphorus, and nitrogen. The fundamental surface chemical decomposition kinetics of selected molecules, especially simulants, are studied on metal and metal oxide substrates that model technological materials used to destroy and render them harmless. Our goal is to acquire fundamental and quantitative molecular level descriptions of heterogeneous chemical reactions at gas-solid interfaces. DTIC

ELECTRICAL CONDUCTIVITY OF ION IMPLANTED LADDER AND SEMI-LADDER POLYMERS Final Report, 1 Sep. 1990 - 31 Oct. 1991

Arthur J. Epstein Oct. 1992 35 p

(Contract F49620-90-C-0072)

(AD-A261401; AFOSR-93-0035TR) Avail: CASI HC A03/MF A01

Aromatic heterocyclic ordered rigid rod, ladder and semi-ladder polymers (including BBL, PBO, and BBB) combine exceptional high temperatures stability with excellent mechanical properties as well as environmental stability. We have carried out systemic coordinated investigation of the morphological, chemical, optical and electrical properties of ion implanted rigid rod, ladder and semi-ladder polymers, XPS data of films reveal significant reduction in the heteroatoms. An increase carbon content after implantation together with the scanning electron microscopy and Raman studies indicate that the implanted material is no longer polymeric but perhaps better described as a carbon network, The implanted polymers have a featureless broad optical absorption from the infrared to the UV. They have a very weakly temperature-dependent conductivity (typically -100 S/cm at room temperature). The initial conductivity, thermoelectric power and magnetotransport studies suggest that these implanted polymers behave as disordered metals. Further studies on are necessary to elucidate the role of implant ion beam energy and current as well as to determine the microscopic charge conduction mechanism. DTIC

TEMPLATE SYNTHESIS OF ELECTRONICALLY CONDUCTIVE POLYMERS: A NEW ROUTE FOR ACHIEVING HIGHER ELECTRONIC CONDUCTIVITIES Interim Technical Report
Charles R. Martin, R. Parthasarathy, and V. Menon 22 Feb. 1993 8 p Submitted for publication Sponsored in part by AFOSR LIMITED REPRODUCIBILITY: More than 20% of this document may be affected by microfiche quality
(Contract N00014-82-K-0612)
(AD-A261616; ONR-TR-82) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We have recently developed a method for synthesizing microscopic fibers and tubules of electronically conductive polymers. This method entails synthesis of the polymer within the pores of a microporous host membrane. Conductivities in the narrowest of these 'template-synthesized' tubules and fibers can be significantly higher than in conventional forms (e.g. powders or thin films) of the analogous polymer. These previous conductivity data were based on a two-point measurement of the resistance of the host membrane after synthesis of the conductive polymer fibers within this membrane. In this paper we will show results of conductivity measurements on thin films composed of the template-synthesized tubules and fibers. A four-point conductivity measurement was used on these thin films. These four-point measurements corroborate the earlier two-point conductivity data and show that the template-synthesized materials are significantly more conductive. DTIC

WORKSHOP ON DIAMOND AND DIAMOND-LIKE-CARBON FILMS FOR THE TRANSPORTATION INDUSTRY
F. A. Nichols, ed. and D. K. Moores, ed. Jan. 1993 385 p Workshop held in Argonne, IL, 4-5 Feb. 1992
(Contract W-31-109-eng-38)
(DE93-007491; CONF-920262) Avail: CASI HC A17/MF A04

Applications exist in advanced transportation systems as well as in manufacturing processes that would benefit from superior tribological properties of diamond, diamond-like-carbon and cubic boron nitride coatings. Their superior hardness make them ideal candidates as protective coatings to reduce adhesive, abrasive and erosive wear in advanced diesel engines, gas turbines and spark-ignited engines and in machining and manufacturing tools as well. The high thermal conductivity of diamond also makes it desirable for thermal management not only in tribological applications but also in high-power electronic devices and possibly large braking systems. A workshop has been recently held at Argonne National Laboratory entitled 'Diamond and Diamond-Like-Carbon Films for Transportation Applications' which was attended by 85 scientists and engineers including top people involved in the basic technology of these films and also representatives from many US industrial companies. A working group on applications endorsed 18 different applications for these films in the transportation area alone. Separate abstracts have been prepared. DOE

PUBLISHED ASSESSMENTS BEARING ON THE FUTURE USE OF CERAMIC SUPERCONDUCTORS BY THE ELECTRIC POWER SECTOR
R. F. Giese and A. M. Wolsky 25 Aug. 1992 157 p
(Contract W-31-109-eng-38)
(DE93-007737; ANL-93007737) Avail: CASI HC A08/MF A02

Much has been written about ceramic superconductors since their discovery in 1986. Most of this writing reports and describes scientific research. However, some authors have sought to put this research in context: to assess where the field stands, what might be technically feasible, what might be economically feasible, and what potential impacts ceramic superconductors will bring to the electric power sector. This report's purpose is to make the results of already published assessments readily available. To that end, this report lists and provides abstracts for various technical and economic assessments related to applications of High-Temperature Superconductors (HTS) to the electric power sector. Those studies deemed most important are identified and summarized. These assessments were identified by two means. First, members of the Executive Committee identified some reports as worthy of consideration and forwarded them to Argonne National Laboratory. Twelve assessments were selected. Each of these is listed and summarized in the following section. Second, a bibliographic search was performed on five databases: INSPEC, NTIS, COMPENDEX, Energy Science & Technology, and Electric Power Database. The search consisted of first selecting all papers related to High Temperature Superconductors. Then papers related to SMES, cables, generators, motors, fault current limiters, or electric utilities were selected. When suitable variants of the above terms were included, this resulted in a selection of 493 citations. These citations were subjected to review by the authors. A number of citations were determined to be inappropriate (e.g., a number referred to digital transmission lines for electronics and communications applications). The reduced list consisted of 200 entries. Each of these citations, with an abstract, is presented in the following sections. DOE

IGNITION AND COMBUSTION OF LUNAR PROPELLANTS Final Technical Report, 11 Jun. 1990 - 10 Jun. 1992
Rodney L. Burton, Ted A. Roberts, and Herman Krier Apr. 1993 317 p
(Grant NAG3-1184)
(NASA-CR-192814; NAS 1.26:192814; AAE-93-04; UIUL-93-0504) Avail: CASI HC A14/MF A03

The ignition and combustion of Al, Mg, and Al/Mg alloy particles in 99 percent O2/1 percent N2 mixtures is investigated at high temperatures and pressures for rocket engine applications. The 20 micron particles contain 0, 5, 10, 20, 40, 60, 80, and 100 weight percent Mg alloyed with Al, and are ignited in oxygen using the reflected shock in a shock tube near the endwall. Using this technique, the ignition delay and combustion times of the particles are measured at temperatures up to 3250 K as a function of Mg content for oxygen pressures of 8.5, 17, and 34 atm. An ignition model is developed which employs a simple lumped capacitance energy equation and temperature and pressure dependent particle and gas properties. Good agreement is achieved between the measured and predicted trends in the ignition delay times. For the particles investigated, the contribution of heterogeneous reaction to the heating of the particle is found to be significant at lower temperatures, but may be neglected as gas temperatures above 3000 K. As little as 10 percent Mg reduces the ignition delay time substantially at all pressures tested. The particle ignition delay times decrease with increasing Mg content, and this reduction becomes less pronounced as oxidizer temperature and pressure are increased.

Efforts to synthesize bimetallic cluster-derived Rh-Mo catalysts for CO and CO2 hydrogenation to preferentially produce oxygenates. The rhodium-molybdenum cluster, (PPh3)2RhMO(CO)(mu-CO)2Cp, was employed as a precursor to alumina- and silica-supported catalysts which were in CO hydrogenation. When compared to catalysts made from the distinct organometallic complexes, RhH(CO)(PPh3)3 and MO(CO)3Cp2, the catalysts derived from a binuclear precursor show higher activities for CO hydrogenation and superior selectivities towards oxygenates, namely, methanol, dimethyl ether, and ethanol. Their product distributions depend on the support. Fourier transform infrared spectroscopy studies indicate that CO chemisorbs on cluster-derived catalysts as gem-dicarbonyls while it is chemisorbed only in the linear-carbonyl configuration on catalysts made from separate rhodium and molybdenum complexes. The particular oxygenate selectivity of the cluster-derived catalysts may be correlated to the strong electronic interaction between Rh and Mo. Carbon dioxide hydrogenation was also carried out on the catalysts mentioned above. Again, the cluster-derived catalysts show higher oxygenate selectivities. Finally, the catalysts were studied with regard to both CO and CO2 hydrogenation kinetics, apparent activation energies inferred. DOE

A NOVEL PROCESS FOR METHANOL SYNTHESIS
J. W. Tierney and I. Wender 1992 12 p
(Contract DE-FG22-89PC-89786)
(DE93-008037; DOE/PC-89786/T14) Avail: CASI HC A03/MF A01

A bench-scale reactor is being used to study the conversion of synthesis gas to methanol (MEOH) in the liquid phase by a novel method. In previous reports, evidence for a two step reaction consisting of a carbonylation reaction taking place mainly in the 'film' close to a copper chromite surface followed by a hydrogenolysis reaction taking place on the surface of the copper chromite was provided. The interaction between the two catalysts enhances the rate of methanol formation. In this quarter, the equilibrium concentration for methyl formate was reexamined and data at higher loadings of copper chromite was obtained. DOE

The goal is to understand the mechanisms of formation of alcohols and other oxygenates from syngas over supported catalysts. Work during this period included: (1) BET (Brunauer, Emmett, and Teller) surface areas and x ray diffraction (XRD) patterns of Cu/ZnO/Al2O3 and Co(5 percent)/Cu/ZnO/Al2O3 suggest that Co did not change the structure; (2) CO was hydrogenated over 10 percent Co catalyst; (3) C2H4 additions increased the isopropanol and decreased the methanol production. Blank runs with H 2/He/CH3OH/C2H4 showed that C2H4 does not react with CH3OH. DOE

EMISSIONS FROM ETHANOL AND LPG FUELED VEHICLES
Mark E. Pitstick 1992 20 p Presented at the 72nd Transportation Research Board Meeting, Washington, DC, 10-14 Jan. 1993
(Contract W-31-109-eng-38)
(DE93-006410; ANL/ES/CP-78570; CONF-930120-4) Avail: CASI HC A03/MF A01

This paper addresses the environmental concerns of using neat ethanol and liquified petroleum gas (LPG) as transportation fuels in the US. Low-levelblends of ethanol (10 percent) with gasoline have been used as fuels in the US for more than a decade, but neat ethanol (85 percent or more) has only been used extensively in Brazil. LPG, which consists mostly of propane, is already used extensively as a vehicle fuel in the US, but its use has been limited primarily to converted fleet vehicles. Increasing US interest in alternative fuels has raised the possibility of introducing neat ethanol vehicles into the market and expanding the number of LPG vehicles. Use of such vehicles and increased production and consumption of fuel ethanol and LPG will undoubtedly have environmental impacts. If the impacts are determined to be severe, they could act as barriers to the introduction of neat ethanol and LPG vehicles. Environmental concerns include exhaust and evaporative emissions and their impact on ozone formation and global warming, toxic emissions from fuel combustion and evaporation, and agricultural emissions from production of ethanol. The paper is not intended to be judgemental regarding the overall attractiveness of ethanol or LPG compared to other transportation fuels. The environmental concerns are reviewed and summarized, but the only conclusion reached is that there is no single concern that is likely to prevent the introduction of neat ethanol fueled vehicles or the increase in LPG fueled vehicles. MAGNITUDE AND VALUE OF ELECTRIC VEHICLE EMISSIONS REDUCTIONS FOR SIX DRIVING CYCLES IN FOUR US CITIES WITH VARYING AIR QUALITY PROBLEMS
Quanlu Wang (California Univ., Davis.) and Danilo L. Santini 1992 28 p Presented at the 72nd Transportation research Board Meeting, Washington, DC, 10-14 Jan. 1993
(Contract W-31-109-eng-38)
(DE93-006417; ANL/ES/CP-77429; CONF-930120-3) Avail: CASI HC A03/MF A01

The emissions of logically competing mid-1990 gasoline vehicles (GV's) and electric vehicles (EV's) are estimated as if the vehicles were driven in the same pattern of driving. Six different driving cycles are evaluated, ranging in speed from 7 to 49 miles per hour (mph). These steps are repeated using specifics of fuel composition, electric power mix, and environmental conditions applicable to Chicago, Denver, Los Angeles, and New York in the month of July. The year 2000 emissions differences for each of four regulated pollutants - HC, CO, NOx, SOx - are estimated. CO2 emissions are also estimated. With use of EV's, HC and CO emissions are consistently lowered by 98 percent or more. CO2 emissions reductions are uniformly large at low speed, but variable at high speed. It is found that initially introduced EV's could achieve 100 percent emission reductions in Chicago by using off-peak power from nuclear power plants for EV electricity generation. Emissions reductions occur for all combinations in Los Angeles, and for most combinations in New York, excepting SOx. NOx emissions are reduced in all four cities. An 'avoided cost' value for each regulated pollutant is estimated for each of the cities. The values for each city depend on severity of air quality violations. It is estimated that the emissions reduction value of EV's driven an average of one and one half hours per day in Los Angeles ranges from $1050 to $3,900; $590 to $2100 in New York; $270 to $1200 in Chicago; and $330 to $1250 in Denver (1989$). Assuming a range of about 100 miles in congested conditions with speeds of 10 mph or less, the estimates range from $3600 to $13300 for Los Angeles; $2004 to $7200 for New York; $930 to $2930 for Chicago; and $1120 to $4290 for Denver. Low estimates are obtained using EPA's draft Mobile5 model for GV emissions, high values by using California's EMFAC7EP-SCF1 model. The dollar value benefit estimates include no economic value. DOE

BIOLOGICAL PRODUCTION OF ETHANOL FROM COAL
Oct. 1992 146 p
(Contract DE-AC22-89PC-89876)
(DE93-008947; DOE/PC-89876/T17) Avail: CASI HC A07/MF A02

The production of ethanol from synthesis gas by the anaerobic bacterium C. ljungdahlii has been demonstrated in continuous stirred tank reactors (CSTRs), CSTRs with cell recycle and trickle bed reactors. Various liquid media were utilized in these studies including basal medium, basal media with 1/2 B-vitamins and no yeast extract and a medium specifically designed for the growth of C. ljungdahlii in the CSTR. Ethanol production was successful in each of the three reactor types, although trickle bed operation with C. ljungdahlii was not as good as with the stirred tank reactors. Operation in the CSTR with cell recycle was particularly promising, producing 47 g/L ethanol with only minor concentrations of the by-product acetate. DOE

(DE93-009183; DOE/MC-27115/3280) Avail: CASI HC A02/MF A01

The objective is to demonstrate the effectiveness of a catalytic membrane reactor (ceramic membrane combined with catalyst) to selectively produce methanol by partial oxidation of methane. None of the membranes tested in a high pressure system could selectively remove methanol, until a cooling tube was inserted inside the membrane reactor to quench the product stream; this effectively increased methanol selectivity 2 times during methane oxidation. For both conditions, combined selectivity for methanol and CO is constant, 85 percent. The remaining product is CO2. The membranes were broken when removed from the system; this was remedied when a cooling tube with a smaller diameter was used. DOE

Syngas is known to contain approximately 1 percent H2S, along with CO, CO2, H2, and CH4. Similarly, the syngas may become contaminated with oxygen, particularly during reactor start-up and during maintenance. Previous studies with the water-gas shift bacterium Rhodospirillum rubrum have shown that the bacterium is tolerant of small quantities of oxygen, but the effects of oxygen on CO-consumption are unknown. Similarly, R. rubrum is known to be tolerant of H2S, with high concentrations of H2S negatively affecting CO-uptake. Batch experiments were thus carried out to determine the effects of H2S and O2 on CO-uptake by R. rubrum. The results of these experiments were quantified by using Monod equations modified by adding terms for CO, H2S, and O2 inhibition. The techniques used in determining kinetic expressions previously shown for other gas-phase substrate bacterial systems including R. rubrum were utilized. DOE

For a long time now experts on energetic materials and munitions have been using experimental tests to evaluate the vulnerability of such materials or munitions, or at least their sensitivity to various stimuli. Yet those tests are far from being representative of the scenarios of accidental or combat stimuli, and the interpretation of them itself sometimes needs to be treated cautiously, given the important decisions that may be made as the results of these trials, for the design of insensitive munitions. A study of many examples, such as bullet impact and cook-off, enables a critical evaluation of those tests and suggests that they be conducted in a more scientific purpose by coupling them with mathematical modeling. It concludes by advocating international cooperation, as the recent NIMIC workshop shows the way, on modeling the tests and their experimental adaptation to the requirements of the models. DTIC

EMERGING TECHNOLOGIES IN ETHANOL PRODUCTION
Neil Hohmann and C. Matthew Rendleman Jan. 1993 19 p
(PB93-157014; USDA/AIB-663) Avail: CASI HC A03/MF A01

The fuel ethanol industry is poised to adopt a wide range of technologies that would reduce costs at every stage of the production process. Improved enzymes and fermenter designs can reduce the time needed to convert corn to ethanol, and they can lower capital costs. Membrane filtration can allow the recovery of high-value coproducts such as lactic acid. Adoption of these and other innovations in the next 5 years is expected in new ethanol plants constructed to cope with new demand resulting from Clean Air Act stipulations for cleaner burning fuel. Biomass (agricultural residues, municipal and yard waste, and energy crops like switch grass) can also be converted to ethanol, although commercial-scale ventures are limited by current technology. While biomass requires more handling and sorting before conversion, those costs may be offset by the abundance of biomass relative to corn. Author (DTIC)

THE BURNING RATE BEHAVIOR OF PURE NITROCELLULOSE PROPELLANT SAMPLES Final Report, Jan. 1979 - Dec. 1981
Frederick W. Robbins and Theresa Keys Mar. 1993 37 p
(DA Proj. 1L1-62618-AH-80)
(AD-A261009) Avail: CASI HC A03/MF A01

Closed bomb firings have been conducted to determine the burning rate behavior of pure nitrocellulose (NC) gun propellants. Samples produced and tested included nitration levels of 12.02, 12.65, 13.11 percent, in both zero and seven-perforated cylindrical geometries. A sample containing basic lead carbonate was also included. Burning rates derived from the closed bomb tests were compared to strand burner data measured on samples extruded from the same NC batches. The burning rate plots for the pure NC samples show the characteristic slope changes of propellants with additives. DTIC

DEVELOPMENT OF A METHOD TO DETERMINE THE AUTOXIDATION OF TURBINE FUELS Final Report, Sep. 1987 - Apr. 1992
George E. Fodor and David W. Naegeli May 1992 255 p
(Contract N00014-87-K-2057)
(AD-A260578; BFLRF-280) Avail: CASI HC A12/MF A03

The report describes the development of a research grade test method that allows the precise evaluation of antioxidants and prediction of the rate of peroxide formation at ambient conditions from data obtained from accelerated oxidation experiments at elevated temperatures. The rates of peroxide formation in 10 model jet fuels were measured at several temperatures ranging from 43 to 120 C, with oxygen partial pressures ranging from approximately 10 to 1140 kPa. Results of rigorously controlled experiments agreed with a kinetic model of the autoxidation process, which showed that the peroxide concentration increased as the square of stress duration. Within the experimental limits, the rate of peroxide formation did not depend on the oxygen partial pressure. Arrhenius correlations of global rate constants determined from peroxide concentration time histories in accordance with the kinetic model showed that a single autoxidation was accountable for the results obtained in the 430 to 120 C temperature range. This method has also been used to evaluate the effectiveness of several hindered phenolic antioxidants to inhibit the formation of peroxides in two jet fuels at temperatures of 100 and 120 C and an oxygen partial pressure of 240 kPa (ca. 20 psig). Antioxidants were evaluated in terms of induction period duration and their rates of peroxide formation during the induction period and the initial linear segment of the post-induction time. The global rate constant for the formation of peroxides during the induction period was reduced by the antioxidant, whereas the post-induction rate remained unchanged. DTIC

EFFECT OF A METAL DEACTIVATOR FUEL ADDITIVE ON FUEL DEPOSITION IN FUEL ATOMIZERS AT HIGH TEMPERATURE Interim Report, Nov. 1990 - Aug. 1992
Clifford A. Moses Aug. 1992 38 p
(Contracts DAAK70-92-C-0059; DAAK70-87-C-0043)
(AD-A260915; BFLRF-281) Avail: CASI HC A03/MF A01

Fuel additives that are metal deactivators have been shown to improve the thermal stability breakpoint temperature of aviation fuels as determined in the Jet Fuel Thermal Oxidation Tester (JFTOT). These additives therefore, offer the opportunity to upgrade fuels of marginal thermal stability. However, concern has been expressed over whether this upgrade would be realized in actual aircraft hardware. To address this concern, an experimental project has been conducted with fuel atomizers from the T700 engine to determine the effect of the additive DMD-2, a metal deactivator, on high-temperature fuel deposition. The tests were conducted with JP-5 fuel supplied by the Naval Air Warfare Center Aircraft Division, Trenton (NAWCADTRN). For some of the tests, the base fuel was contaminated with copper to a concentration between 400 and 500 ppb. In the uncontaminated fuel, the metal deactivator (MDA) additive was tested at a concentration of 1 ppm; in the contaminated fuel, MDA concentrations of 1 ppm and 5.7 ppm were tested. With uncontaminated fuel, the results showed that initially the additive significantly reduced the deposition rate, but then, after an induction period, the deposition rate sharply increased. With the copper-contaminated fuel, at 1 ppm, the additive showed a small effect, but did not completely passivate the copper. At 5.7 ppm, there was no significant deposition during the test, indicating the copper was passivated. It is concluded that the metal deactivators inhibit deposition for a period of time until the surface becomes coated with carbon deposition, and then, they no longer serve any function. These results are consistent with some single-tube heat exchanger experiments reported in the literature. DTIC

FUNDAMENTAL STUDIES OF DROPLET INTERACTIONS IN DENSE SPRAYS Final Report, 1 Nov. 1989 - 31 Oct. 1992
W. A. Sirignano, S. E. Elghobashi, I. Kim, and C. H. Chiang 31 Dec. 1992 136 p
(Grant AF-AFOSR-0064-90)
(AD-A261165; AFOSR-TR-93-0073) Avail: CASI HC A07/MF A02

The research addressed interactions amongst droplets in a dense spray. The effects of neighboring droplets, that were a few droplet diameters away, on a vaporizing droplet were examined by theoretical and computational analyses for two basic configurations: (1) the axisymmetric convective situation where two or three droplets moved in tandem and (2) the fully three-dimensional convective situation where droplets moved side-by-side. Droplets in the wake of other droplets experienced a reduction in drag force, transport rates, and vaporization rate, sometimes causing collisions. Sufficiently close droplets moving side-by-side, approximately in parallel, experienced a repulsive lift force and an increased drag force. Vaporizing liquid oxygen droplets in a hydrogen gas environment were studied at both subcritical and supercritical pressures considering the variable liquid density with the associated droplet swelling during heating and the dependence of the local critical state upon local composition. Droplet surface conditions could be subcritical even if pressures were supercritical for pure oxygen due to diffusing hydrogen. The critical surface regressed towards the droplet surface as the droplet heated. Engineering correlations for the drag coefficients, Nusselt numbers, and Sherwood numbers for hydrocarbon fuel droplets in dense sprays were obtained. DTIC

INFLUENCE OF SUPERCRITICAL CONDITIONS ON PRE-COMBUSTION CHEMISTRY AND TRANSPORT BEHAVIOR OF JET FUELS Final Report, 9 Jul. 1992 - 9 Jan. 1993
Anantha Krishnan Feb. 1993 60 p
(Contract F49620-92-C-0030)
(AD-A261813; CFDRC-4240/2; AFOSR-93-0137TR) Avail: CASI HC A04/MF A01

The objective of the Phase 1 study was to investigate heat transfer characteristics in supercritical flows. Detailed models were formulated to compute transport properties (such as density, conductivity, viscosity, and specific heat) in the supercritical regime. The models were incorporated into a general purpose Computational Fluid Dynamics (CFD) code capable of modeling flow, heat transfer, and reactions in complex geometries. Two and three-dimensional simulations were performed for supercritical flow and heat transfer in a test cell. Parallel experimental work was done by

Professor L. D. Chen at the University of Iowa. The results of the Phase 1 work show that there is considerable augmentation of heat transfer near the critical point. Also, the large variation in density across the critical point has a significant effect on the near wall profiles of velocity and temperature. Ideal gas approximations of supercritical flows can result in gross errors in predicting heat transfer rates. The development of this supercritical transport model provides a basis for incorporating complex models for pre-combustion chemistry in jet fuels. DTIC

ENERGETIC MATERIALS FROM CUBANE Final Technical Report, 1 Aug. 1985 - 31 Jul. 1992
Philip E. Eaton 16 Feb. 1993 5 p
(Contract N00014-84-K-0645)
(AD-A261317) Avail: CASI HC A01/MF A01

New generations of highly energetic materials are required for the modern Navy. Cubane is a very dense, exceptionally energetic hydrocarbon; its heat of formation, density, and strain energy are all extraordinarily high--in combination unexceeded by any other stable hydrocarbon. This dense, energetic system has 8 identical methine C-H groups at which hydrogen may be replaced by energy-rich substituents. The goal of this project is to understand the fundamental properties of the basic set of reactive intermediates that might be used for the functionalization of the cubane nucleus. Only cubane-1,4-dicarboxylic acid is available readily. Ways to introduce other substituents elsewhere on the cubane nucleus are needed. As cubanes are far from the ordinary in their chemical behavior, this necessitates the development of radically new methodology. DTIC

THERMAL DECOMPOSITION OF ENERGETIC MATERIALS. 4: DEUTERIUM ISOTOPE EFFECTS AND ISOTOPIC SCRAMBLING CONDENSED-PHASED DECOMPOSITION OF 1,3,5-TRINITROHEXAHYDRO-S-TRIAZINE Special Publication
Richard Behrens, Jr. and Suryanarayana Bulusu Feb. 1993 15 p
Sponsored by ARO and Army Armament Research, Development and Engineering Center
(AD-A261804; ARAED-SP-92004) Avail: CASI HC A03/MF A01

The inter- versus intramolecular origin of the products formed in the thermal decomposition of 1,3,5-trinitrohexahydro-s-triazine (RDX) has been traced by isotopic crossover experiments using mixtures of differently labeled analogues of RDX. The isotopic analogues of RDX used in the experiments include H-2, C-13, N-15, and O-18. The fraction of isotopic scrambling and the extent of the deuterium kinetic isotope effect (DKIE) are reported for the different thermal decomposition products. Isotopic scrambling is not observed for the N-N bond in N2O and only in small amounts (7%) in the C-H bonds in CH2O, consistent with a mechanism of their formation through methylene nitramine precursors. A product, oxy-s-triazine (OST, C3H3N3O), does not undergo isotopic scrambling in H/D, N-14/N-15, or C-14/O-18 experiments, and its rate of formation exhibits a DKIE of 1.5. These results are consistent with the formation of OST via unimolecular decomposition of RDX. Another product, 1-nitroso-3,5-dinitrohexahydro-s-triazine (ONDNTA, C3H6N6O5), is found to be formed with complete scrambling of the N-NO bond, suggesting an N-N bond cleavage and a radical recombination process in its formation. One of the hydrogen containing products, H2O, exhibits a DKIE of 1.5 +/- 0.1. In contrast, CH2O and ONDNTA have DKIEs of 1.05 +/- 0.1 and 1.05 +/- 0.2, respectively, indicating that hydrogen transfer is not involved in the rate-limiting step of the reaction pathway leading to the formation of these products. MOLECULAR COMPOSITION, STRUCTURE, AND SENSITIVITY OF EXPLOSIVES
C. B. Storm and J. R. Travis 1992 14 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-36)
(DE93-003850; LA-UR-92-3823; CONF-921101-14) Avail: CASI HC A03/MF A01

High explosives, blasting agents, propellants, and pyrotechnics are all metastable relative to reaction products and are termed energetic materials. They are thermodynamically unstable but the kinetics of decomposition at ambient conditions are sufficiently slow that they can be handled safely under controlled conditions. The ease with which an energetic material can be caused to undergo a violent reaction or detonation is called its sensitivity. Sensitivity tests for energetic materials are aimed at defining the response of the material to a specific situation, usually prompt shock initiation or a delayed reaction in an accident. The observed response is always due to a combination of the physical state and the molecular structure of the material. Modeling of any initiation process must consider both factors. The physical state of the material determines how and where the energy is deposited in the material. The molecular structure determines the mechanism of decomposition of the material and the rate of energy release. Slower inherent reaction chemistry leads to longer reaction zones in detonation and inherently safer materials. Slower chemistry also requires hot spots involved in initiation to be hotter and to survive for longer periods of time. High thermal conductivity also leads to quenching of small hot spots and makes a material more difficult to initiate. Early endothermic decomposition chemistry also delays initiation by delaying heat release to support hot spot growth. The growth to violent reaction or detonation also depends on the nature of the early reaction products. If chemical intermediates are produced that drive further accelerating autocatalytic decomposition the initiation will grow rapidly to a violent reaction. DOE

MILITARY STANDARDIZATION HANDBOOK: AIRCRAFT REFUELING HANDBOOK
20 Oct. 1992 105 p
(AD-A261755; MIL-HDBK-844(AS)) Avail: CASI HC A06/MF A02

This handbook provides basic information on the properties and characteristics of aviation fuels along with general information on the standards, equipment, and operating principals related to the handling of these fuels at Navy and Marine Corps activities. It is designed to supplement the NATOPS AIRCRAFT REFUELING MANUAL, NATOPS 00-80T-109, by providing background information and guidance on the requirements and procedures contained in the NATOPS Manual. The contents are limited to technical and operational information of a general nature. Specific operating procedures and equipment requirements are contained in the NATOPS AIRCRAFT REFUELING MANUAL, NATOPS 00-80T-109. Accounting and stock control procedures are not included. There are basically two different types of aircraft fuels in use at Navy and Marine Corps air activities - turbine engine fuels and aviation gasolines (AVGAS). A knowledge of some of the basic properties and characteristics of these fuels is necessary in understanding the importance of delivering the proper fuel to the aircraft. Such knowledge is also valuable in understanding the need for safety and caution in handling aviation fuels. DTIC

ELECTRODEPOSITION IN LOW GRAVITY Ph.D. Thesis
Hind Malaeb Abi-Akar 1992 214 p
Avail: Univ. Microfilms Order No. DA9306835

Materials development and enhancement is paramount to the advancement of science and the growing demand for new materials. The possibility of enhancing metal coatings by production in a low G environment was investigated in this work. Ni and Co metal films were produced by electrodeposition, with emphasis on the former. High deposition rates, encompassing or exceeding 80 mA/cm(sup 2) produced an anomalous form of Ni which was microcrystalline or amorphous by an x-ray criterion. Employed deposition conditions under reduced gravity seemed to mimic the results quenching techniques utilized in producing amorphous metals and metallic alloys. Electrocodeposition of particles and metals was also part of this research. Ni-diamond and Co-chromium carbide systems were studied. Reduced gravity proved to eliminate sedimentation and edge affects and promote easier particle dispersion in the electrolyte, yielding uniformly distributed particles in the metal matrix. This environment codeposited higher volume percentage of large nonconducting particles (45 micron diamond) than produced on earth under similar conditions. The opposite was found for submicron diamond. Custom designed and constructed experimental packages and state-of-the-art electronics were utilized to perform this experimentation. These experiments accumulated and compared data from flights on a KC-135 airplane, four Consort sounding rockets, and one shuttle mission. Dissert. Abstr.

A MODEL OF CONCURRENT FLOW FLAME SPREAD OVER A THIN SOLID FUEL
Paul V. Ferkul Apr. 1993 156 p
(Grant NAG3-1046; RTOP 674-22-05)
(NASA-CR-191111; E-7726; NAS 1.26:191111) Avail: CASI HC A08/MF A02

A numerical model is developed to examine laminar flame spread and extinction over a thin solid fuel in lowspeed concurrent flows. The model provides a more precise fluid-mechanical description of the flame by incorporating an elliptic treatment of the upstream flame stabilization zone near the fuel burnout point. Parabolic equations are used to treat the downstream flame, which has a higher flow Reynolds number. The parabolic and elliptic regions are coupled smoothly by an appropriate matching of boundary conditions. The solid phase consists of an energy equation with surface radiative loss and a surface pyrolysis relation. Steady spread with constant flame and pyrolysis lengths is found possible for thin fuels and this facilitates the adoption of a moving coordinate system attached to the flame with the flame spread rate being an eigen value. Calculations are performed in purely forced flow in a range of velocities which are lower than those induced in a normal gravity buoyant environment. Both quenching and blowoff extinction are observed. The results show that as flow velocity or oxygen percentage is reduced, the flame spread rate, the pyrolysis length, and the flame length all decrease, as expected. The flame standoff distance from the solid and the reaction zone thickness, however, first increase with decreasing flow velocity, but eventually decrease very near the quenching extinction limit. The short, diffuse flames observed at low flow velocities and oxygen levels are consistent with available experimental data. The maximum flame temperature decreases slowly at first as flow velocity is reduced, then falls more steeply close to the quenching extinction limit. Low velocity quenching occurs as a result of heat loss. At low velocities, surface radiative loss becomes a significant fraction of the total combustion heat release. In addition, the shorter flame length causes an increase in the fraction of conduction downstream compared to conduction to the fuel. These heat losses lead to lower flame temperatures, and ultimately, extinction. This extinction mechanism differs from that of blowoff, where the flame is unable to be stabilized due to the high flow velocity. Author

NASA MICROGRAVITY SCIENCE AND APPLICATIONS PROGRAM Annual Report, 1992
1992 48 p
(NASA-TM-108775; NAS 1.15:108775) Avail: CASI HC A03/MF A01

Key elements of the microgravity research program as conducted by the Microgravity Science and Applications Division (MSAD) within the Office of Space Science and Applications (OSSA) during fiscal year (FY) 1992 are described. This NASA funded program supported investigators from the university, industry, and government research communities. The program's goals, the approach taken to achieve those goals, and the resources that were available are summarized. It provides a 'snapshot' of the Program's status at the end of FY 1992 and reviews highlights and progress in the ground and flight-based research during the year. It also describes four major space missions that flew during FY 1992, the advanced technology development (ATD) activities, and the plans to use the research potential of Space Station Freedom and other advanced carriers. The MSAD program structure encompassed five research areas: (1) Biotechnology, (2) Combustion Science, (3) Fluid Physics, (4) Materials Science, and (5) Benchmark Physics. Author (revised)

WHISKER GROWTH STUDIES UNDER CONDITIONS WHICH RESEMBLE THOSE AVAILABLE ON AN ORBITING SPACE STATION
Final Technical Report, 1 Jun. 1990 - 31 Dec. 1992
Herman H. Hobbs 31 Dec. 1992 16 p
(Grant NAG3-1142)
(NASA-CR-192701; NAS 1.26:192701) Avail: CASI HC A03/MF A01

Minimal funding was provided by NASA with one designated 'mission' being the clear demonstration of the relevance of previously supported whisker growth studies to microgravity research. While in one sense this work has shown the converse, namely, that ambient gravitational fields as high as 1 Earth normal have no relevance to growth of whiskers by hydrogen reduction of metal halides, a case is made that this does not demonstrate lack of relevance to microgravity research. On the contrary, the driving forces for this growth are precisely those which must be understood in order to understand growth in microgravity. The results described suggest that knowledge gained from this work may be highly fundamental to our understanding of the genesis of metal crystals. Time and money ran out before this work could be considered complete. At least another year's study and analysis will be required before publications could be justified. Author

LASER IGNITION APPLICATION IN A SPACE EXPERIMENT
Larry C. Liou and Dennis E. Culley Apr. 1993 15 p Presented at the OE/LASE'93 Conference, Los Angeles, CA, 19-20 Jan. 1993; sponsored by the Society of Photo-Optical Instrumentation Engineers
(RTOP 694-03-08)
(NASA-TM-106133; E-7805; NAS 1.15:106133) Avail: CASI HC A03/MF A01

A laser ignition system is proposed for the Combustion Experiment Module on an orbiting spacecraft. The results of a design study are given using the scheduled 'Flame Ball Experiment' as the design guidelines. Three laser ignition mechanisms and wavelengths are evaluated. A prototype laser is chosen and its specifications are given, followed by consideration of the beam optical arrangement, the ignition power requirement, the laser ignition system weight, size, reliability, and laser cooling and power consumption. Electromagnetic interference to the onboard electronics caused by the laser ignition process is discussed. Finally, ground tests are suggested. Author (revised)

MODELING OF BUBBLE AND DROP FORMATION IN FLOWING LIQUIDS IN TERRESTRIAL AND MICROGRAVITY ENVIRONMENTS Ph.D. Thesis
Iee-Hwan Kim 1992 201 p
Avail: Univ. Microfilms Order No. DA9236330

A theoretical model for the process of bubble and drop formation, which is applicable for both terrestrial and microgravity environments, has been developed by using a force balance. Two different flow systems are considered in which a nozzle is located either horizontally (co-flow system) or vertically (cross-flow system) in a flowing liquid through a pipe. The contact angle variation at the nozzle due to the inertia of the flowing liquid has been theoretically analyzed. The added mass coefficient of the bubble moving through a pipe is obtained analytically based on potential flow theory. The bubble formation process is assumed to take place in two stages, the expansion stage and the detachment stage. The important forces in a bubble formation process are nondimensionalized and the bubble motions during its expansion and detachment stages for the two different flow systems are analyzed by using nondimensional variables. The predictions of the present model are compared with available experimental results in the case of normal gravity and the agreement is satisfactory. The present model is applied for a gas-liquid system to estimate the bubble size for various conditions in microgravity. The effect of the nondimensional variables as well as the flow systems on the bubble size have been evaluated. The present model is also applied for the prediction of the flow pattern transition from bubble to slug flow in microgravity. The predictions are compared with the results of microgravity experiment and of groundbased experiment. It is indicated that flow patterns in microgravity are closely related to the bubble formation process as well as the entrance configuration. The predictions of the present model for the transition from bubble to slug flow show good qualitative agreement with experimental results. Dissert. Abstr.

MODELLING OF MICROGRAVITY IGNITION PHENOMENA Ph.D. Thesis
Changjin Lee 1992 154 p
Avail: Univ. Microfilms Order No. DA9236514

The structure and stability of flame balls and the characteristics of the outwardly propagating spherical flames of sub-limit mixtures are studied both analytically and numerically in the context of an asymptotic analysis in which theta approaches infinity, and (1 - Le) = O(1/theta), where theta is the activation energy and Le is Lewis number. For flame balls, the heat loss mechanism necessary for stable solutions is the radiation from burnt gas. If heat loss is less than quenching value, there are two stationary solutions, but the small branch solution is always unstable to the one dimensional disturbances regardless of Lewis number when Le is less than or equal to 1. And the large branch solution is stable within a certain range of heat loss, if Lewis number is less than the critical Lewis number Le(sub c) (Le less than Le(sub c) less than 1). The flame balls with sufficiently large radius are always unstable to three dimensional disturbances, independent of Le. These results, therefore, reveal that flame balls can only be possible if Le is less than Le(sub c) where Le(sub c) is identified very close to unity. The three dimensional stability is not Lewis number but near field heat losses driven. For spherically propagating flames, the evolution of flame after the flame initiation subject to radiative heat loss and confinement effect (pressure rise of unburned mixture due to finite chamber volume) was studied using numerical calculation of asymptotically derived model. The Lewis number effect (Le less than 1) enhances flame intensity but radiative cooling attenuates the intensity through the inflow velocity behind flame front. The pressure rise enhances the burning as flame radius is comparable to the chamber radius. The exchange of these two competitive mechanism leads to self-extinguishing flames (SEF's), and the confinement effect causes flames to be extremely sensitive to the intial data. Dissert. Abstr.

GRAVITY-DEPENDENT TRANSPORT PHENOMENA IN ZEOLITE CRYSTAL GROWTH Ph.D. Thesis
Hao Zhang 1992 123 p
Avail: Univ. Microfilms Order No. DA9236352

It has been thought that large zeolite crystals with perfect quality can be grown in microgravity environments due to avoidance of particle settling and elimination of natural convection. However, there has been no detailed quantitative study in the literature to determine the nature and extent of these effects. We investigated the related transport phenomena to see if they play important roles in zeolite crystal growth. Natural convection due to temperature and concentration gradients is analyzed by estimating thermal and solutal Grashof numbers. The results suggest that the effect of natural convection on zeolite syntheses is negligible even on the earth. Moreover, several different effects caused by sedimentation are studied herein. The shear stress at the growing surface due to settling and buoyancy driven natural convection is shown to be many orders of magnitude smaller than that due to vessel shaking. Therefore, there is no reason to believe that the shear stress caused by particle settling and natural convection has a significant effect on the sizes of resultant zeolite crystals. Furthermore, it is commonly thought that because of crystal settling a nutrient-poor crystal sediment is formed at the bottom of the reactor where growth terminates. However, the settiing itself may help transfer more nutrient to the growing surface than diffusion alone can, thereby accelerating the growth rate. Zeolite crystal growth is a unique process which usually takes place within an amorphous solid gel plus an aqueous solution. It is found herein that, under normal gravity, a white opaque gel portion containing amorphous solid gel, crystals and aqueous solution shrinks to the bottom of the hydrothermal reactor due to depletion of the flocculated gel particles. A correlation for the shrinkage is derived which agrees very well with experimental observations. Also, a non-dimensional parameter is suggested as a criterion for the occurrence of gravity-caused secondary nucleation which has been believed to result in smaller crystal size. In addition, zeolite crystal growth under microgravity is discussed in terms of under what conditions reduced gravity might be beneficial based on our analyses.

The gel structure and behavior in the absence of a gravitational force is preliminary explored, which suggests the mass transfer rate will be reduced at microgravity. Dissert. Abstr.

THE SYSTEMS ENGINEERING OVERVIEW AND PROCESS (FROM THE SYSTEMS ENGINEERING MANAGEMENT GUIDE, 1990)
In NASA, Washington, Readings in Systems Engineering 1993 p 9-15 (For primary document see N93-24678 09-31)
Avail: CASI HC A02/MF A03

The past several decades have seen the rise of large, highly interactive systems that are on the forward edge of technology. As a result of this growth and the increased usage of digital systems (computers and software), the concept of systems engineering has gained increasing attention. Some of this attention is no doubt due to large program failures which possibly could have been avoided, or at least mitigated, through the use of systems engineering principles. The complexity of modern day weapon systems requires conscious application of systems engineering concepts to ensure producible, operable and supportable systems that satisfy mission requirements. Although many authors have traced the roots of systems engineering to earlier dates, the initial formalization of the systems engineering process for military development began to surface in the mid-1950s on the ballistic missile programs. These early ballistic missile development programs marked the emergence of engineering discipline 'specialists' which has since continued to grow. Each of these specialties not only has a need to take data from the overall development process, but also to supply data, in the form of requirements and analysis results, to the process. A number of technical instructions, military standards and specifications, and manuals were developed as a result of these development programs. In particular, MILSTD-499 was issued in 1969 to assist both government and contractor personnel in defining the systems engineering effort in support of defense acquisition programs. This standard was updated to MIL-STD499A in 1974, and formed the foundation for current application of systems engineering principles to military development programs.

SYSTEMS ENGINEERING FOR VERY LARGE SYSTEMS
Paul E. Lewkowicz *In* NASA, Washington, Readings in Systems Engineering 1993 p 17-22 (For primary document see N93-24678 09-31)
Avail: CASI HC A02/MF A03

Very large integrated systems have always posed special problems for engineers. Whether they are power generation systems, computer networks or space vehicles, whenever there are multiple interfaces, complex technologies or just demanding customers, the challenges are unique. 'Systems engineering' has evolved as a discipline in order to meet these challenges by providing a structured, top-down design and development methodology for the engineer. This paper attempts to define the general class of problems requiring the complete systems engineering treatment and to show how systems engineering can be utilized to improve customer satisfaction and profit ability. Specifically, this work will focus on a design methodology for the largest of systems, not necessarily in terms of physical size, but in terms of complexity and interconnectivity.

WHAT IS A SYSTEM? NASA'S PHASED PROJECT DESCRIPTION
In NASA, Washington, Readings in Systems Engineering 1993 p 23-34 (For primary document see N93-24678 09-31)
Avail: CASI HC A03/MF A03

NASA phase A and B projects are addressed. The Phase A study is the preliminary analysis of a space concept. These concepts could have come from a pre-Phase A study or from other sources within or external to NASA. The majority of concepts that are studied at MSFC are assigned by NASA Headquarters and funded accordingly. The overall program schedule depicts important milestones that establish the start and finish dates of each study phase, including design, development, launch, and operations. The Phase B of the project consists of the refinement of preliminary requirements, cost estimates, schedules and risk assessments prior to starting final design and development. The goal of a concept definition activity is to determine the best and most feasible concept(s) that will satisfy the mission and science requirements.

MANAGEMENT ISSUES IN SYSTEMS ENGINEERING
Robert Shishko, Robert G. Chamberlain, Robert Aster, Vincent Bilardo, Kevin Forsberg, Hal Mooz, Lou Polaski, and Ron Wade *In* NASA, Washington, Readings in Systems Engineering 1993 p 35-77 (For primary document see N93-24678 09-31)
Avail: CASI HC A03/MF A03

When applied to a system, the doctrine of successive refinement is a divide-and-conquer strategy. Complex systems are sucessively divided into pieces that are less complex, until they are simple enough to be conquered. This decomposition results in several structures for describing the product system and the producing system. These structures play important roles in systems engineering and project management. Many of the remaining sections in this chapter are devoted to describing some of these key structures. Structures that describe the product system include, but are not limited to, the requirements tree, system architecture and certain symbolic information such as system drawings, schematics, and data bases. The structures that describe the producing system include the project's work breakdown, schedules, cost accounts and organization.

SPACECRAFT SYSTEMS ENGINEERING: AN INTRODUCTION TO THE PROCESS AT GSFC
Tony Fragomeni and Michael G. Ryschkewitsch *In* NASA, Washington, Readings in Systems Engineering 1993 p 79-86 (For primary document see N93-24678 09-31)
Avail: CASI HC A02/MF A03

The main objective in systems engineering is to devise a coherent total system design capable of achieving the stated requirements. Requirements should be rigid. However, they should be continuously challenged, rechallenged and/or validated. The systems engineer must specify every requirement in order to design, document, implement and conduct the mission. Each and every requirement must be logically considered, traceable and evaluated through various analysis and trade studies in a total systems design. Margins must be determined to be realistic as well as adequate. The systems engineer must also continuously close the loop and verify system performance against the requirements. The fundamental role of the systems engineer, however, is to engineer, not manage. Yet, in large, complex missions, where more than one systems engineer is required, someone needs to manage the systems engineers, and we call them 'systems managers.' Systems engineering management is an overview function which plans, guides, monitors and controls the technical execution of a project as implemented by the systems engineers. As the project moves on through Phases A and B into Phase C/D, the systems engineering tasks become a small portion of the total effort. The systems management role increases since discipline subsystem engineers are conducting analyses and reviewing test data for final review and acceptance by the systems managers.

THE SE ROLE IN ESTABLISHING, VERIFYING AND CONTROLLING TOP-LEVEL PROGRAM REQUIREMENTS
Charles W. Mathews *In its* Readings in Systems Engineering 1993 p 105-114 (For primary document see N93-24678 09-31)
Avail: CASI HC A02/MF A03

The program objectives and requirements described in the preceding paragraphs emphasize mission demonstrations. Obtaining desired science or applications information is another type of program objective. The program requirements then state the need for specific data, usually specifying a particular instrument or instrument set; the operating conditions under which the data is to be obtained (e.g., orbit altitude, field of view, and pointing accuracy); and the data handling and use. Conversely, a new instrument may be conceived or created with the program objective to establish its use potential. The Multispectral Scanner employed in the Landsat program is an example. THE IMPORTANCE OF COST CONSIDERATIONS IN THE SYSTEMS ENGINEERING PROCESS
John D. Hodge *In its* Readings in Systems Engineering 1993 p 115-125 (For primary document see N93-24678 09-31)
Avail: CASI HC A03/MF A03

This paper examines the question of cost, from the birth of a program to its conclusion, particularly from the point of view of large multi-center programs, and suggests how to avoid some of the traps and pitfalls. Emphasis is given to cost in the systems engineering process, but there is an inevitable overlap with program management. (These terms, systems engineering and program management, have never been clearly defined.) In these days of vast Federal budget deficits and increasing overseas competition, it is imperative that we get more for each research and development dollar. This is the only way we will retain our leadership in high technology and, in the long run, our way of life. Derived from text

OPTIMIZATION IN THE SYSTEMS ENGINEERING PROCESS
Loren A. Lemmerman *In* NASA, Washington, Readings in Systems Engineering 1993 p 173-179 (For primary document see N93-24678 09-31)
Avail: CASI HC A02/MF A03

The essential elements of the design process consist of the mission definition phase that provides the system requirements, the conceptual design, the preliminary design and finally the detailed design. Mission definition is performed largely by operations analysts in conjunction with the customer. The result of their study is handed off to the systems engineers for documentation as the systems requirements. The document that provides these requirements is the basis for the further design work of the design engineers at the Lockheed-Georgia Company. The design phase actually begins with conceptual design, which is generally conducted by a small group of engineers using multidisciplinary design programs. Because of the complexity of the design problem, the analyses are relatively simple and generally dependent on parametric analyses of the configuration. The result of this phase is a baseline configuration from which preliminary design may be initiated. Derived from text

THE INITIAL FLIGHT ANOMALIES OF SKYLAB 1 **c18**

In its Readings in Systems Engineering 1993 p 181-199 (For primary document see N93-24678 09-31)

Avail: CASI HC A03/MF A03

At approximately 63 seconds into the flight of Skylab 1 on May 14, 1973, an anomaly occurred which resulted in the complete loss of the meteoroid shield around the orbital workshop. This was followed by the loss of one of the two solar array systems on the workshop and a failure of the inter stage adapter to separate from the S-II stage of the Saturn V launch vehicle. The investigation reported herein identified the most probable cause of this flight anomaly to be the breakup and loss of the meteoroid shield due to aerodynamic loads that were not accounted for in its design. The breakup of the meteoroid shield, in turn, broke the tie downs that secured one of the solar array systems to the workshop. Complete loss of this solar array system occurred at 593 seconds when the exhaust plume of the S-II stage retro-rockets impacted the partially deployed solar array system. Falling debris from the meteoroid shield also damaged the S-II inter stage adapter ordnance system in such a manner as to preclude separation. Of several possible failure modes of the meteoroid shield that were identified, the most probable in this particular flight was internal pressurization of its auxiliary tunnel which acted to force the forward end of the meteoroid shield away from the shell of the workshop and into the supersonic air stream. The pressurization of the auxiliary tunnel was due to the existence of several openings in the aft region of the tunnel. Another possible failure mode was the separation of the leading edge of the meteoroid shield from the shell of the workshop (particularly in the region of the folded ordnance panel) of sufficient extent to admit ram air pressures under the shield. REPORT OF THE SEASAT FAILURE REVIEW BOARD **c18**

In its Readings in Systems Engineering 1993 p 201-215 (For primary document see N93-24678 09-31)

Avail: CASI HC A03/MF A03

The Seasat spacecraft failed on October 9, 1978, after satisfactory operation in orbit for 105 days, as a result of a loss of electrical power in the Agena bus that was used as a part of the spacecraft. The loss of power was caused by a massive and progressive short in one of the slip ring assemblies that was used to connect the rotating solar arrays into the power subsystem. The most likely cause of this short was the initiation of an arc between adjacent slip ring brush assemblies. The triggering mechanism of this arc could have been either a wire-to-brush assembly contact, a brush-to-brush contact, or a momentary short caused by a contaminant that bridged internal components of opposite electrical polarity. COMPRESSOR CALORIMETER PERFORMANCE OF REFRIGERANT BLENDS: COMPARATIVE METHODS AND RESULTS FOR A REFRIGERATOR/FREEZER APPLICATION

C. K. Rice and J. R. Sand Jan. 1993 32 p Presented at the Winter Meeting of the American Society of Heating, Refrigeration and Air Conditioning Engineers, Chicago, IL, 23-27 Jan. 1993

(Contract DE-AC05-84OR-21400)

(DE93-006734; CONF-930118-4) Avail: CASI HC A03/MF A01

A protocol was developed to define calorimeter operating pressures for nonazeotropic refrigerant mixtures (NARM's) which corresponded with the saturated evaporator and condenser temperatures commonly used for pure refrigerants. Compressor calorimeter results were obtained using this equivalent-mean-temperature (EMT) approach and a generally applied Association of Home Appliance Manufacturers (AHAM) procedure at conditions characteristic of a domestic refrigerator-freezer application. Tests with R-12 and two NARM's indicate that compressor volumetric and isentropic efficiencies are nearly the same for refrigerants with similar capacities and pressure ratios. The liquid-line temperature conditions specified in the AHAM calorimeter rating procedure for refrigerator-freezer compressors were found to preferentially derate NARM performance relative to R-12. Conversion of calorimeter data taken with a fixed liquid-line temperature to a uniform minimal level of condenser subcooling is recommended as a fairer procedure when NARM's are involved. Compressor energy-efficiency-ratio (EER) and capacity data measured as a result of the EMT approach were compared to system performance calculated using an equivalent heat exchanger loading (EHXL) protocol based on a Lorenz-Meutzner (L-M) refrigerator-freezer modeling program. The EHXL protocol was used to transform the calorimeter results into a more relevant representation of potential L-M cycle performance. The EMT method used to set up the calorimeter tests and the AHAM liquid-line conditions combined to significantly understate the cycle potential of NARM's relative to that predicted at the more appropriate EHXL conditions. Compressor conditions representative of larger heat exchanger sizes were also found to give a smaller L-M cycle advantage relative to R-12. DOE

A SURVEY OF LIFE SUPPORT SYSTEM AUTOMATION AND CONTROL

Cory K. Finn Jan. 1993 11 p

(RTOP 199-61-12)

(NASA-TM-103977; A-92191; NAS 1.15:103977) Avail: CASI HC A03/MF A01

The level of automation and control necessary to support advanced life support systems for use in the manned space program is steadily increasing. As the length and complexity of manned missions increase, life support systems must be able to meet new space challenges. Longer, more complex missions create new demands for increased automation, improved sensors, and improved control systems. It is imperative that research in these key areas keep pace with current and future developments in regenerative life support technology. This paper provides an overview of past and present research in the areas of sensor development, automation, and control of life support systems for the manned space program, and it discusses the impact continued research in several key areas will have on the feasibility, operation, and design of future life support systems. HEAT TRANSFER IN ROTATING SERPENTINE PASSAGES WITH SELECTED MODEL ORIENTATION FOR SMOOTH OR SKEWED TRIP WALLS

B. V. Johnson (United Technologies Research Center, East Hartford, CT.), J. H. Wagner (United Technologies Research Center, East Hartford, CT.), G. D. Steuber (Pratt and Whitney Aircraft, East Hartford, CT.), and F. C. Yeh Apr. 1993 10 p Prepared for presentation at the 38th International Gas Turbine and Aeroengine Congress and Exposition, Cincinnati, OH, 24-27 May 1993; sponsored by ASME

(RTOP 505-62-52)

(NASA-TM-106126; E-7793; NAS 1.15:106126) Avail: CASI HC A02/MF A01

Experiments were conducted to determine the effects of model orientation as well as buoyancy and Coriolis forces on heat transfer in turbine blade internal coolant passages. Turbine blades have internal coolant passage surfaces at the leading and trailing edges of the airfoil with surfaces at angles which are as large as +/- 50 to 60 degrees to the axis of rotation. Most of the previously-presented, multiple-passage, rotating heat transfer experiments have focused on radial passages aligned with the axis of rotation. Results from serpentine passages with orientations 0 and 45 degrees to the axis of rotation which simulate the coolant passages for the mid chord and trailing edge regions of the rotating airfoil are compared. The experiments were conducted with rotation in both directions to simulate serpentine coolant passages with the rearward flow of coolant or with the forward flow of coolant. The experiments were conducted for passages with smooth surfaces and with 45 degree trips adjacent to airfoil surfaces for the radial portion of the serpentine passages. At a typical flow condition, the heat transfer on the leading surfaces for flow outward in the first passage with smooth walls was twice as much for the model at 45 degrees compared to the model at 0 degrees. However, the differences for the other passages and with trips were less. In addition, the effects of buoyancy and Coriolis forces on heat transfer in the rotating passage were decreased with the model at 45 degrees, compared to the results at 0 degrees. The heat transfer in the turn regions and immediately downstream of the turns in the second passage with flow inward and in the third passage with flow outward was also a function of model orientation with

differences as large as 40 to 50 percent occurring between the model orientations with forward flow and rearward flow of coolant. Author

THE EVALUATION OF TECHNICAL MODELS USED FOR MAJOR-ACCIDENT HAZARD INSTALLATIONS. REPORT TO COMMISSION OF THE EUROPEAN COMMUNITIES DIRECTORATE GENERAL 12
R. E. Britter Aug. 1991 46 p
(CUED/A-AERO/TR-19) Avail: CASI HC A03/MF A01

Models are used in many ways by individuals and organizations within the European Community. Within the context of major technological hazards decisions of considerable importance are based wholly, or partly, on these models. The quality, that is the fitness-for-purpose, of these models will differ and there is obviously an interest in both the relative quality of one model against another and the absolute quality of any particular model. This leads to the evaluation of model quality and to methods by which model quality might be improved. It is noted that models are a principal method for the transfer of technology but also that the nature, role, and limitations of models is frequently misunderstood. There is a widespread demand for guidance on model quality and consequently on the development of evaluation techniques. The CEC is an appropriate body to have a role in the study of the quality and the management of quality of technical models. The evaluation of the quality of technical models entails: (1) an assurance of correct coding of algorithms is required and this is probably straightforward; (2) a statistical model validation is required and this entails comparison with experimental data sets (considerable care is required in performing such a validation, in particular in determination of an appropriate protocol to ensure unambiguous conclusions to be drawn from the validation); and (3) a model assessment including a scientific review and other less objective aspects is also required and should be given equal weight to a statistical model validation. Actions which may lead to an improvement in model quality are presented. Author

MALONE REFRIGERATION
G. W. Swift 1992 6 p Presented at the 6th International Stirling Engine Conference and Exhibition, Rotterdam, Netherlands, 26-28 May 1993
(Contract W-7405-eng-36)
(DE93-005439; LA-UR-92-4136; CONF-930525-1) Avail: CASI HC A02/MF A01

Malone refrigeration is the use of a liquid near its critical point, without evaporation, as the working fluid in a refrigeration cycle such as the Stirling cycle. We discuss relevant properties of appropriate liquids, and we describe two Malone refrigerators. The first, which was completed several years ago, established the basic principles of use for liquids in such cycles. The second, now under construction, is a linear, free-piston machine. DOE

HAZARDS OF EXPLOSIVES DUSTS: PARTICLE SIZE EFFECTS
K. L. Cashdollar, M. Hertzberg, and G. M. Green Feb. 1992 39 p
(Contract DE-AI01-90EH-89084)
(DE93-009380; DOE/EH-89084/T8) Avail: CASI HC A03/MF A01

At the request of the Department of Energy, the Bureau of Mines has investigated the hazards of military explosives dispersed as dust clouds in a 20-L test chamber. In this report, the effect of particle size for HMX, HNS, RDX, TATB, and TNT explosives dusts is studied in detail. The explosibility data for these dusts are also compared to those for pure fuel dusts. The data show that all of the sizes of the explosives dusts that were studied were capable of sustaining explosions as dust clouds dispersed in air. The finest sizes (less than 10 micron) of explosives dusts were less reactive than the intermediate sizes (20 to 60 micron); this is opposite to the particle size effect observed previously for the pure fuel dusts. At the largest sizes studied, the explosives dusts become somewhat less reactive as dispersed dust clouds. The six sizes of the HMX dust were also studied as dust clouds dispersed in nitrogen. DOE

RECOMMENDATIONS FOR A KALMAN FILTER TO ESTIMATE AND CONTROL FREEZE AND SUBLIME RATES OF GASEOUS DIFFUSION PLANT FREEZER/SUBLIMER SYSTEMS
F. R. Ruppel Sep. 1992 43 p
(Contract DE-AC05-84OR-21400)
(ORNL/TM-12183) Avail: CASI HC A03/MF A01

The purpose of gaseous diffusion plant freezer/sublimer systems is to control the inventory of UF6 in the process cascade. When it is desired to decrease process inventory, UF6 vapor is transferred from the process cascade into the freezer/sublimer and frozen out. When it is desired to increase process inventory, UF6 is sublimed out of the freezer/sublimer and transferred back to the process cascade. This process technology has proven to be economically attractive for gaseous diffusion plants because it enables the plant to increase power usage during periods of low electrical utility demands, such as at night when inexpensive, nonfirm power is available, and decrease power usage during periods of high electrical utility demands. Power usage is proportional to process inventory. Control of freeze rate and sublime rate is important to this operation, especially when several freezer/sublimer systems must operate in harmony during a major inventory swing. The purpose of this report is to recommend an improved method to estimate and control the freeze and sublime rates of freezer/sublimer systems. Author (revised)

A method and apparatus uniformly impregnate stranded material with dry powder such as low solubility, high melt flow polymer powder to produce, for example, composite prepregs. The stranded material is expanded in an impregnation chamber by an influx of air so that the powder, which may enter through the same inlet as the air, penetrates to the center of the stranded material. The stranded material then is contracted for holding the powder therein. The stranded material and powder may be pulled through the impregnation chamber in the same direction by vacuum. Larger particles of powder which do not fully penetrate the stranded material may be combed into the stranded material and powder which does not impregnate the stranded material may be collected and reused.

FINITE ELEMENT MODELING OF THE HYDROFORMING PRESS Final Report
M. G. Schrank and W. H. Smith Dec. 1992 29 p
(Contract DE-AC04-76DP-00613)
(KCP-613-4999) Avail: CASI HC A03/MF A01

Three-dimensional finite element analyses were conducted to simulate a sheet metal forming process. An explicit transient dynamics finite element code was used to analyze the essentially quasi-static process. In order to obtain numerical results in a reasonable time frame, the process was modeled in a substantially compressed time period. Analytical results were compared with data obtained from experimental forming trials. Predicted wrinkling patterns, as well as distribution of plastic strain, compared favorably with available experimental data. Author

AMPHIB: A USERS MANUAL Technical Report, Jan. 1992 - Dec. 1992
Devadatta Mukutmoni, Yogendra K. Joshi, and Matthew D. Kelleher 25 Jan. 1993 113 p
(AD-A261769; NPS-ME-93-001) Avail: CASI HC A06/MF A02

A general purpose three-dimensional code (AMPHIB) that solves electronic cooling problems is documented. In its present structure, the code is set up for computations in liquid immersion cooling of an m by n array of chips embedded in a substrate in a three-dimensional rectangular enclosure. Nevertheless, it can be modified to solve problems in forced, mixed and natural convection for a wide range of boundary conditions. The subroutines and the input are described in detail. A listing of the code and sample example problems are also included. DTIC

This quarterly publication provides archival reports on developments in programs managed by JPL's Office of Telecommunications and Data Acquisition (TDA). In space communications, radio navigation, radio science, and ground-based radio and radar astronomy, it reports on activities of the Deep Space Network (DSN) in planning, supporting research and technology, implementation, and operations. Also included are standards activity at JPL for space data and information systems and reimbursable DSN work performed for other space agencies through NASA. For individual titles, see N93-24660 through N93-24671.

FEASIBILITY STUDY OF A Ka-/Ka-BAND DICHROIC PLATE WITH STEPPED RECTANGULAR APERTURES
J. C. Chen *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 1-7 (For primary document see N93-24659 09-32)
(RTOP 310-20-64-86-02)
Avail: CASI HC A02/MF A02

For the Cassini spacecraft mission, a dichroic plate is needed to pass Ka-band uplink (34.2 to 34.7 GHz) and to reflect Ka-band downlink (31.8 to 32.3 GHz) for dual-frequency operation in the Deep Space Network. The special characteristic of the Ka-/Ka-band dichroic plate is that the pass band and the reflective band are only 1.9 GHz (5.7 percent) apart. A thick dichroic plate with stepped rectangular apertures that function as resonator filters was chosen for the Ka-/Ka-band dichroic plate design. The results of the feasibility study are presented in this article. Author

A TECHNIQUE FOR COMPUTATION OF NOISE TEMPERATURE DUE TO A BEAM WAVEGUIDE SHROUD
W. Veruttipong and M. M. Franco *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 8-16 (For primary document see N93-24659 09-32)
(RTOP 310-20-65-86-02)
Avail: CASI HC A02/MF A02

Direct analytical computation of the noise temperature of real beam waveguide (BWG) systems, including all mirrors and the surrounding shroud, is an extremely complex problem and virtually impossible to achieve. Yet the DSN antennas are required to be ultra low-noise in order to be effective, and a reasonably accurate prediction is essential. This article presents a relatively simple technique to compute a real BWG system noise temperature by combining analytical techniques with data from experimental tests. Specific expressions and parameters for X-band (8.45-GHz) BWG noise computation are obtained for DSS 13 and DSS 24, now under construction. These expressions are also valid for various conditions of the BWG feed systems, including horn sizes and positions, and mirror sizes, curvatures, and positions. Parameters for S- and Ka-bands (2.3 and 32.0 GHz) have not been determined; however, those can be obtained following the same procedure as for X-band. Author

SOFT DECODING A SELF-DUAL (48, 24; 12) CODE **c61**
G. Solomon *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 17-18 (For primary document see N93-24659 09-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A01/MF A02

A self-dual (48,24;12) code comes from restricting a binary cyclic (63,18;36) code to a 6 x 7 matrix, adding an eighth all-zero column, and then adjoining six dimensions to this extended 6 x 8 matrix. These six dimensions are generated by linear combinations of row permutations of a 6 x 8 matrix of weight 12, whose sums of rows and columns add to one. A soft decoding using these properties and approximating maximum likelihood is presented here. This is preliminary to a possible soft decoding of the box (72,36;15) code that promises a 7.7-dB theoretical coding under maximum likelihood. Author (revised)

A (72, 36; 15) BOX CODE **c61**
G. Solomon *In its* The Telecommunications and Data Acquisition Report 19-21 (SEE N93-24659 09-32) 15 Feb. 1993 (For primary document see N93-24659 09-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A01/MF A02

A (72,36;15) box code is constructed as a 9 x 8 matrix whose columns add to form an extended BCH-Hamming (8,4;4) code and whose rows sum to odd or even parity. The newly constructed code, due to its matrix form, is easily decodable for all seven-error and many eight-error patterns. The code comes from a slight modification in the parity (eighth) dimension of the Reed-Solomon (8,4;5) code over GF(512). Error correction uses the row sum parity information to detect errors, which then become erasures in a Reed-Solomon correction algorithm. Author

THE ANALYSIS OF CONVOLUTIONAL CODES VIA THE EXTENDED SMITH ALGORITHM **c61**
R. J. McEliece and I. Onyszchuk *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 22-30 (For primary document see N93-24659 09-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A02/MF A02

Convolutional codes have been the central part of most error-control systems in deep-space communication for many years. Almost all such applications, however, have used the restricted class of (n,1), also known as 'rate 1/n,' convolutional codes. The more general class of (n,k) convolutional codes contains many potentially useful codes, but their algebraic theory is difficult and has proved to be a stumbling block in the evolution of convolutional coding systems. In this article, the situation is improved by describing a set of practical algorithms for computing certain basic things about a convolutional code (among them the degree, the Forney indices, a minimal generator matrix, and a parity-check matrix), which are usually needed before a system using the code can be built. The approach is based on the classic Forney theory for convolutional codes, together with the extended Smith algorithm for polynomial matrices, which is introduced in this article. Author

Avail: CASI HC A02/MF A02

The application of two wavelet transforms to image compression is discussed. It is noted that the Haar transform, with proper bit allocation, has performance that is visually superior to an algorithm based on a Daubechies filter and to the discrete cosine transform based Joint Photographic Experts Group (JPEG) algorithm at compression ratios exceeding 20:1. In terms of the root-mean-square error, the performance of the Haar transform method is basically comparable to that of the JPEG algorithm. The implementation of the Haar transform can be achieved in integer arithmetic, making it very suitable for applications requiring real-time performance. Author (revised)

FAILURE MONITORING IN DYNAMIC SYSTEMS: MODEL CONSTRUCTION WITHOUT FAULT TRAINING DATA **c38**
P. Smyth and J. Mellstrom *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 37-49 (For primary document see N93-24659 09-32)
(RTOP 310-20-65-91-00)
Avail: CASI HC A03/MF A02

Advances in the use of autoregressive models, pattern recognition methods, and hidden Markov models for on-line health monitoring of dynamic systems (such as DSN antennas) have recently been reported. However, the algorithms described in previous work have the significant drawback that data acquired under fault conditions are assumed to be available in order to train the model used for monitoring the system under observation. This article reports that this assumption can be relaxed and that hidden Markov monitoring models can be constructed using only data acquired under normal conditions and prior knowledge of the system characteristics being measured. The method is described and evaluated on data from the DSS 13 34-m beam wave guide antenna. The primary conclusion from the experimental results is that the method is indeed practical and holds considerable promise for application at the 70-m antenna sites where acquisition of fault data under controlled conditions is not realistic. A FUNCTIONAL DESCRIPTION OF THE BUFFERED TELEMETRY DEMODULATOR (BTD) **c17**
H. Tsou, B. Shah, R. Lee, and S. Hinedi *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 50-73 (For primary document see N93-24659 09-32)
(RTOP 314-30-61-02-02)
Avail: CASI HC A03/MF A02

This article gives a functional description of the buffered telemetry demodulator (BTD), which operates on recorded digital samples to extract the symbols from the received signal. The key advantages of the BTD are as follows: (1) its ability to reprocess the signal to reduce acquisition time; (2) its ability to use future information about the signal and to perform smoothing on past samples; and (3) its minimum transmission bandwidth requirement as each sub carrier harmonic is processed individually. The first application of the BTD would be the Galileo S-band contingency mission, where the signal is so weak that reprocessing to reduce the acquisition time is crucial. Moreover, in the event of employing antenna arraying with full spectrum combining, only the sub carrier harmonics need to be transmitted between sites, resulting in significant reduction in data rate transmission requirements. Software implementation of the BTD is described for various general-purpose computers. Author (revised)

SYMBOL SIGNAL-TO-NOISE RATIO LOSS IN SQUARE-WAVE SUBCARRIER DOWNCONVERSION
Y. Feria and J. Statman *In its* The Telecommunications and Data Acquisition Report 74-82 (SEE N93-24659 09-32) 15 Feb. 1993 (For primary document see N93-24659 09-32)
(RTOP 314-30-42-10-89)
Avail: CASI HC A02/MF A02

This article presents the simulated results of the signal-to-noise ratio (SNR) loss in the process of a square-wave subcarrier down conversion. In a previous article, the SNR degradation was evaluated at the output of the down converter based on the signal and noise power change. Unlike in the previous article, the SNR loss is defined here as the difference between the actual and theoretical symbol SNR's for the same symbol-error rate at the output of the symbol matched filter. The results show that an average SNR loss of 0.3 dB can be achieved with tenth-order infinite impulse response (IIR) filters. This loss is a 0.2-dB increase over the SNR degradation in the previous analysis where neither the signal distortion nor the symbol detector was considered. Author (revised)

DESIGN OF THE REDUCED LQG COMPENSATOR FOR THE DSS-13 ANTENNA
W. Gawronski *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 83-106 (For primary document see N93-24659 09-32)
(RTOP 314-40-41-10-15)
Avail: CASI HC A03/MF A02

A linear-quadratic-Gaussian (LQG) compensator design procedure is proposed for the DSS-13 antenna. The procedure is based on two properties. It is shown that tracking and flexible motion of the antenna are almost independent (the separation property). As a consequence, compensators for the flexible and tracking parts can be designed separately. It is shown also that the balanced LQG compensator's effort is evenly divided between the controller and the estimator. This allows a minimization of the compensator order, which is important for implementation purposes. An efficient compensator reduction procedure that gives a stable low-order compensator of satisfactory performance is introduced. This approach is illustrated with a detailed compensator design for the DSS-13 antenna. The implementation of this compensator design requires an update of the antenna model. Author

PERFORMANCE RESULTS OF A 300-DEGREE LINEAR PHASE MODULATOR FOR SPACEBORNE COMMUNICATIONS APPLICATIONS
N. R. Mysoor and R. O. Mueller *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 107-116 (For primary document see N93-24659 09-32)
(RTOP 314-30-55-30-01)
Avail: CASI HC A02/MF A02

A phase modulator capable of large linear phase deviation, low loss, and wide band operation with good thermal stability was developed for deep space spacecraft transponder (DST) applications at X-band (8.415 GHz) and Ka-band (32 GHz) downlinks. The design uses a two-stage circulator-coupled reflection phase shifter with constant gamma hyperabrupt varactors and an efficient modulator driver circuit to obtain a phase deviation of +/-2.5 rad with better than 8 percent linearity. The measured insertion loss is 6.6 dB +/- 0.35 dB at 8415 MHz. Measured carrier and relative sideband amplitudes resulting from phase modulation by sine wave and square modulating functions agree well with the predicted results.

MANAGEMENT OF SPACE NETWORKS
R. W. Markley and B. F. Williams *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1993 p 117-133 (For primary document see N93-24659 09-32)
(RTOP 316-30-19-41-04)
Avail: CASI HC A03/MF A02

NASA has proposed missions to the Moon and Mars that reflect three areas of emphasis: human presence, exploration, and space resource development for the benefit of Earth. A major requirement for such missions is a robust and reliable communications architecture. Network management--the ability to maintain some degree of human and automatic control over the span of the network from the space elements to the end users on Earth--is required to realize such robust and reliable communications. This article addresses several of the architectural issues associated with space network management. Round-trip delays, such as the 5- to 40-min delays in the Mars case, introduce a host of problems that must be solved by delegating significant control authority to remote nodes. Therefore, management hierarchy is one of the important architectural issues. The following article addresses these concerns, and proposes a network management approach based on emerging standards that covers the needs for fault, configuration, and performance management, delegated

control authority, and hierarchical reporting of events. A relatively simple approach based on standards was demonstrated in the DSN 2000 Information Systems Laboratory, and the results are described. Author

LOW-FREQUENCY ROOM RESPONSES. PART 1: BACKGROUND AND QUALITATIVE CONSIDERATIONS

R. Walker 1992 18 p

(BBC-RD-1992/8-Pt-1) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

The problems inherent in the reproduction of high-quality sound in relatively small rooms are discussed. Methods of predicting the inevitably uneven low-frequency response from source to listener or microphone are also discussed. It is concluded that, even with perfect prediction methods, there would still be some compromises which could only be resolved by making subjective judgements. The use of additional low-frequency loudspeakers in control rooms permits an extra degree of freedom in the positioning of the loudspeakers to obtain the maximum degree of uniformity in response without compromising the stereophonic image localization. Author

LOW-FREQUENCY ROOM RESPONSES. PART 2: CALCULATION METHODS AND EXPERIMENTAL RESULTS

R. Walker 1992 23 p Original contains color illustrations

(BBC-RD-1992/9-Pt-2) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

The development of a relatively simple method for predicting low-frequency responses for near-rectangular rooms based on the summation of modal responses and their coupling coefficients for the source and receiver positions is outlined. Comparisons between calculated and measured responses show that many of the response features can be reproduced. The question of optimum room shape is also addressed, and a method of illustrating the effects of room shape on the low-frequency modal distribution is developed. This uses a single criterion to plot contours of 'room quality' as a function of proportions. Author

THE DESIGN OF A MODULAR SOUND ABSORBER FOR VERY LOW FREQUENCIES

J. A. Fletcher 1992 15 p

(BBC-RD-1992/10) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

Studios and sound control rooms usually have their walls acoustically treated to control the reverberation time. In the BBC, this treatment often takes the form of modular absorbers of which there are a number of BBC designed types for sound absorption in different frequency bands. This report describes an investigation of the feasibility of a modular absorber for the 50 - 100 Hz frequency range. A method of measuring absorption coefficient over a continuous frequency range using a standing wave duct is described. This allows a single modular absorber to be tested instead of requiring a batch of prototypes to be constructed for a reverberation room test. This technique was used to test a variety of absorbers, including porous, Helmholtz, and membrane types. These tests led to a design of membrane absorber, and a small batch of prototypes was constructed and tested in a reverberation room. This test verified that the prototype module had useful absorption in the frequency range of interest. Author

A MODULAR WIDEBAND SOUND ABSORBER

G. D. Plumb 1992 15 p

(BBC-RD-1992/11) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

The absorption coefficients were measured of various depths of RW2 grade Rockwool laid directly on the floor of the ISO-Standard reverberation room at BBC Research Department. The Rockwool was very effective as a wideband sound absorber. A new absorber was designed and tested, having the dimensions of the existing BBC type A modular absorbers and containing RW2 Rockwool. The new absorber has a smoother absorption coefficient curve, a less complicated construction, and weighs less than the existing BBC wideband absorber (type A8/A9). It has been named type A11 and has an equivalent performance to that of BBC type A2 and A3 absorbers combined. It complements, very well, the performance of the A10 very low frequency absorber, described in a companion Report (BBC RD No. 1992/10). Author

THE CONSTANT CURRENT LOOP: A NEW PARADIGM FOR RESISTANCE SIGNAL CONDITIONING

Karl F. Anderson 1993 16 p Proposed for presentation at the Instrument Society of America 39th International Instrumentation Symposium, Albuquerque, NM, 3-6 May 1993

(NASA-TM-108744; NAS 1.15:108744) Avail: CASI HC A03/MF A01

A practical, single, constant-current loop circuit for the signal conditioning of variable-resistance transducers was synthesized, analyzed, and demonstrated. The strain gage and the resistance temperature device are examples of variable-resistance sensors. Lead wires connect variable-resistance sensors to remotely located signal-conditioning hardware. The presence of lead wires in the conventional Wheatstone bridge signal-conditioning circuit introduces undesired effects that reduce the quality of the data from the remote sensors. A practical approach is presented for suppressing essentially all lead wire resistance effects while indicating only the change in resistance value. Theoretical predictions supported by laboratory testing confirm the following features of the approach: (1) the dc response; (2) the electrical output is unaffected by extremely large variations in the resistance of any or all lead wires; (3) the electrical output remains zero for no change in gage resistance; (4) the electrical output is inherently linear with respect to gage resistance change; (5) the sensitivity is double that of a Wheatstone bridge circuit; and (6) the same excitation and sense wires can serve multiple independent gages. An adaptation of the current loop circuit is presented that simultaneously provides an output signal voltage directly proportional to transducer resistance change and provides temperature information that is unaffected by transducer and lead wire resistance variations. These innovations are the subject of NASA patent applications. Author (revised)

A LOW-COMPLEXITY AND HIGH PERFORMANCE CONCATENATED CODING SCHEME FOR HIGH-SPEED SATELLITE COMMUNICATIONS

Shu Lin, DoJun Rhee, and Sandeep Rajpal 1 Feb. 1993 12 p

(Grant NAG5-931)

(NASA-CR-192715; Rept-93-001; NAS 1.26:192715) Avail: CASI HC A03/MF A01

This report presents a low-complexity and high performance concatenated coding scheme for high-speed satellite communications. In this proposed scheme, the NASA Standard Reed-Solomon (RS) code over GF(2(exp 8) is used as the outer code and the second-order Reed-Muller (RM) code of Hamming distance 8 is used as the inner code. The RM inner code has a very simple trellis structure and is decoded with the soft-decision Viterbi decoding algorithm. It is shown that the proposed concatenated coding scheme achieves an error performance which is comparable to that of the NASA TDRS concatenated coding scheme in which the NASA Standard rate-1/2 convolutional code of constraint length 7 and d sub free = 10 is used as the inner code. However, the proposed RM inner code has much smaller decoding complexity, less decoding delay, and much higher decoding speed. Consequently, the proposed concatenated coding scheme is suitable for reliable high-speed satellite communications, and it may be considered as an alternate coding scheme for the NASA TDRS system. THE ATC EVALUATION OF THE PROTOTYPE AIRPORT SURVEILLANCE RADAR WIND SHEAR PROCESSOR (ASR-WSP) AT ORLANDO INTERNATIONAL AIRPORT Final Report

Radame Martinez Mar. 1993 21 p

(DOT/FAA/CT-TN92/48) Avail: CASI HC A03/MF A01

The Airport Surveillance Radar Wind Shear Processor (ASR-WSP), also known as Airport Surveillance Radar-9 (ASR-9) modification for low

altitude wind shear detection, is a production ASR-9 with an expanded weather channel for added processing capabilities. The primary mission of the ASR-WSP is to enhance the safety of air travel through the timely detection and reporting of hazardous wind shear in and near the terminal approach and departure zones of the airport. It will also improve the management of air traffic (AT) in the terminal area through the forecast of precipitation, and ultimately the detection of other hazardous weather phenomena. The ASR-WSP may be used as a stand-alone system at airports without a Terminal Doppler Weather Radar (TDWR) or Enhanced-Low Level Wind Shear Alert System (E-LLWAS), or in an integrated mode with either or both the TDWR and E-LLWAS. An operational evaluation of a prototype ASR-WSP, developed by Massachusetts Institute of Technology Lincoln Laboratories (MIT/LL), was conducted at the Orlando International Airport (MCO) in Orlando, Florida, during the period 29 Jun. to 31 Aug. 1992. The objective of the evaluation was to obtain Federal Aviation Administration (FAA) air traffic controller reaction to the prototype ASR-WSP weather data and display equipment. The following are highlights of the evaluation: (1) the ASW-WSP is very useful when making runway configuration changes; (2) the ASR-WSP is not perceived to be as accurate as the prototype TDWR; (3) the gust front prediction feature is not reliable; and (4) the information provided on both the RDT and the GSD is very useful. AN EXAMPLE OF A PHASE-SEGREGATED ENHANCED PAL BROADCASTING SYSTEM

M. G. Croll, J. O. Drewery, J. E. Easterbrook, R. Storey, and G. A. Thomas 1992 59 p Original contains color illustrations

(BBC-RD-1992/6) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

An enhanced phase alteration line (PAL) system is described which is fully compatible with the terrestrial broadcast system B/G, having a 5 MHz bandwidth. Elimination of luminance/chrominance cross-effects is achieved using the principle of phase-segregation which also allows enhanced luminance resolution. The source picture has a 16:9 aspect ratio and appears on the compatible display as a full letterbox, occupying three-quarters of the display height. Subjective assessment of critical picture material shows a significant improvement over conventional PAL, aside from the wider aspect ratio, whilst phase distortion in the transmission path does not re-introduce cross-effects. AN OUTGOING ENERGY FLUX BOUNDARY CONDITION FOR FINITE DIFFERENCE ICRP ANTENNA MODELS

D. B. Batchelor and M. D. Carter Nov. 1992 20 p

(DE93-007788; ORNL/TM-12248) Avail: CASI HC A03/MF A01

For antennas at the ion cyclotron range of frequencies (ICRF), modeling in vacuum can now be carried out to a high level of detail such that shaping of the current straps, isolating septa, and discrete Faraday shield structures can be included. An efficient approach would be to solve for the fields in the vacuum region near the antenna in three dimensions by finite methods and to match this solution at the plasma-vacuum interface to a solution obtained in the plasma region in one dimension by Fourier methods. This approach has been difficult to carry out because boundary conditions must be imposed at the edge of the finite difference grid on a point-by-point basis, whereas the condition for outgoing energy flux into the plasma is known only in terms of the Fourier transform of the plasma fields. A technique is presented by which a boundary condition can be imposed on the computational grid of a three-dimensional finite difference, or finite element, code by constraining the discrete Fourier transform of the fields at the boundary points to satisfy an outgoing energy flux condition appropriate for the plasma. The boundary condition at a specific grid point appears as a coupling to other grid points on the boundary, with weighting determined by a kernel calculated from the plasma surface impedance matrix for the various plasma Fourier modes. This boundary condition was implemented in a finite difference solution of a simple problem in two dimensions, which can also be solved directly by Fourier transformation. Results are presented, and it is shown that the proposed boundary condition does enforce outgoing energy flux and yields the same solution as is obtained by Fourier methods. DOE

THE PACSAT COMMUNICATIONS EXPERIMENT (PCE) Final Report, 13 Aug. 1990 - 12 Feb. 1992

12 Feb. 1993 6 p

(Contract DE-FG01-90CE-33017)

(DE93-008185; DOE/CE-33017/T1) Avail: CASI HC A02/MF A01

While VITA (Volunteers in Technical Assistance) is the recognized world leader in low earth orbiting (LEO) satellite technology (below 1 GHz), its involvement in communications technologies is to facilitate renewable energy technology transfer to developing countries. A communications payload was incorporated into the UoSat 2 satellite (Surrey Univ., UK), launched in 1984; a prototype satellite (PCE) was also launched Jan 1990. US DOE awarded a second grant to VITA to design and test the prototype ground stations (command and field), install field ground stations in several developing country sites, pursue the operational licensing process, and transfer the evaluation results to the design of an operating system. The principal tasks of the grant are discussed. DOE

FREQUENCY DIVERSITY SIDELOBE CANCELLER Patent

Ben H. Cantrell, inventor (to Navy) 10 Nov. 1992 7 p Filed 19 Feb. 1975

(AD-D015647; US-Patent-5,162,805; US-Patent-Appl-SN-550097) Avail: US Patent and Trademark Office

A new system and technique for cancelling interference in frequency agile receiving systems are described. Main and auxiliary signals are supplied to a pair of multiple loop side-lobe cancellers which are capable of being tuned to different frequencies. At the same time, under the control of a timing clock, plural frequencies are selected and multiplexed between two channels at the time of a radar pulse transmission. The side-lobe cancellers and radar are coupled to the channels such that each canceller operates at a given frequency for two consecutive pulse periods, with the radar transmitting at said given frequency during the second pulse period. By continuously cycling between the two channels, each canceller is operating at the proper frequency to cancel interference even though the radar is changing frequency on a pulse to pulse basis. PROPAGATION AT MICROWAVE FREQUENCIES IN THE PRESENCE OF TROPOSPHERIC STRATIFIED LAYERS Ph.D. Thesis

Gail D. Lochtie 1991 268 p

Avail: Univ. Microfilms Order No. BRD-97210

The problem of determining the attenuation between a transmitter and receiver, in the presence of a horizontally stratified troposphere, is examined for microwave frequencies. Existing tropospheric propagation models are discussed and their limitations are considered. From consideration of measured meteorological parameters, a tri-linear piecewise profile is deemed a reasonable representation of the refractive index profile. Models are developed which simulate the tropospheric refractive index by bi-linear and tri-linear functions. These models provide a closed form solution to the boundary value problem when an arbitrary radiating source is included. The attenuation predictions obtained from the bi-linear and tri-linear models are compared with concurrently measured refractive index and radio signal data. This was carried out for a number of periods where the observed attenuation was considerably less than the normal diffraction level. This comparison has shown that, in cases where horizontal homogeneity is assumed to hold, the tri-linear model provides a considerable improvement over the bi-linear simulation. Dissert. Abstr.

EXPERIMENTS WITH THE HIVITS HDTV CONTRIBUTION CODED

A. D. R. Cotton and N. D. Wells 1992 11 p
(BBC-RD-1992/12) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

As more and more programs are made in high definition television (HDTV) formats, so the need to provide complete production facilities will increase. An important part of television production is the ability to transmit very high quality television signals over long distances for program contribution purposes. For example, this may be from an outside broadcast unit to a television studio center or a transatlantic satellite link for a live television interview. The BBC Research Department, in collaboration with Thomson-CSF/LER and TRT, a French subsidiary of Philips, as part of the RACE HIVITS project, has participated in the construction of 140 Mbit/s contribution-quality bit-rate reduction codec for the transmission of digital HDTV. This report describes the codec architecture, some of the problems that have arisen out of the necessity to perform parallel processing, results from buffer regulation optimization experiments, and results from the field trials conducted over satellite links. The architecture of this equipment was specially developed to allow the generation of an implementation-independent bit stream. The current equipment based on six conventional definition bit-rate reduction codecs working in parallel, will perform equally well with future generations of equipment based on fewer processing units operating in parallel. Indeed, the output bit stream is equivalent to a suitably scaled version of the current ETSI and CMTT standards for the coding of conventional definition television.

MICROWAVE ABSORPTION MEASUREMENTS AND INTERFERENCE: EFFECTS FOR A LIQUID FUEL BETWEEN 2.5 AND 18 GHz
Donald A. Wiegand and Frank Murray Feb. 1993 20 p
(AD-A260607; ARAED-TR-92023) Avail: CASI HC A03/MF A01

The incident, reflected and transmitted powers were measured and the reflection and transmission coefficients calculated for a liquid fuel. Two sizes of double-ridge waveguide were used to cover the frequency ranges 2.5 to 7.5 and 7.5 to 18 GHz and corrections were made for waveguide losses. Strong interference effects were observed and the real part of the dielectric constant was obtained primarily from the separation of interference maxima and minima. The loss tangent was obtained by curve fitting to the normalized power loss, and the absorption coefficient was calculated as a function of frequency from the dielectric data. DTIC

Phonology is traditionally seen as the discipline that concerns itself with the building blocks of linguistic messages. It is the study of the structure of sound inventories of languages and of the participation of sounds in rules or processes. Phonetics, in contrast, concerns speech sounds as produced and perceived. Two extreme positions on the relationship between phonological messages and phonetic realizations are represented in the literature. One holds that the primary home for linguistic symbols, including phonological ones, is the human mind, itself housed in the human brain. The second holds that their primary home is the human vocal tract. DTIC

GIGABIT NETWORK COMMUNICATIONS RESEARCH Quarterly Status Report No. 8, 1 Jul. - 30 Sep. 1992
30 Sep. 1992 11 p
(Contract DABT63-91-C-0001)
(AD-A260644) Avail: CASI HC A03/MF A01

The ATOMIC project utilizes inexpensive fine-grain multicomputer components to create a multi-gigabit per second local area network. This is a unique approach that leverages recent DARPA-supported research at Caltech by Professor Charles Seitz and his students. That research has already produced dense and extremely fast Mosaic single-chip multicomputer nodes. ATOMIC is a unique example of network development that grows upwards from multicomputer machine networking into the domain of a LAN. The principal concerns for this quarter were the continued integration of the new SPARCstation ATOMIC SBus card, modification of the Address Consultant to recognize SBus hosts, and testing of the 3x3 ATOMIC mesh. DISTORTION MEASUREMENTS ON BANDPASS FILTERS WITH POWDERED IRON TOROIDAL INDUCTORS
A. Sarti Jun. 1992 23 p
(AD-A260790; SRL-0076-TM; DODA-AR-006-752) Avail: CASI HC A03/MF A01

This paper reports the results of measurements of both in-band and out-of-band non-linear distortion for an 11-18 MHz bandpass filter which used powdered iron toroidal cores for the inductors. The results are compared with those from a bandpass filter of the same specification using air cored inductors. It is shown that a performance comparable in linearity to the air cored inductor case can be obtained with appropriately sized powdered iron toroidal cores, while still realizing to some extent the advantages of magnetic self shielding and smaller volume that are usually associated with the use of toroidal cores. HIGH-PERFORMANCE VISUALIZATION APPLIED TO COMPUTATIONAL ELECTROMAGNETICS: METHOD-OF-MOMENTS ON A SILICON GRAPHICS WORKSTATION Final Report, Oct. 1991 - Sep. 1992
L. C. Russell and J. W. Rockway Oct. 1992 56 p
(AD-A260820; NRAD-TR-1564) Avail: CASI HC A04/MF A01

This investigation applied advanced visualization techniques to an existing computational electromagnetic code. The goal was to demonstrate that high-performance visualization can improve the utility of computational techniques used in ship electromagnetic designs. The code used was the Numerical Electromagnetics Code Method of Moments (NEC-MoM). The visualization platform was a Silicon Graphics 4D workstation. Two codes were developed to do pre- and post-processing visualization on NEC-MoM. This report lists several benefits that have resulted, or will result, from work done on this Independent Exploratory Development (IED) project. DTIC

ELECTROELASTIC EQUATIONS FOR ELECTRODED THIN PLATES SUBJECT TO LARGE DRIVING VOLTAGES
H. F. Tiersten 18 Jan. 1993 17 p
(Contract DAAL03-92-G-0123)
(AD-A261123; ARO-30378.3-EG-URI) Avail: CASI HC A03/MF A01

Existing rotationally invariant electroelastic equations are reduced to the case of large electric fields and small strain. These latter equations are specialized to the case of thin plates with completely electroded major surfaces, and it is shown that in this case the charge equation of electrostatics is satisfied trivially to lowest order. It is further shown that for the thin stress-free polarized ferroelectric ceramic plate subject to large electric fields, the resulting equations readily account for experimental data in existence in the literature. SIGNAL PROCESSING IN IMPULSIVE ELECTROMAGNETIC INTERFERENCE
Serena M. Zabin 31 Dec. 1992 6 p
(Contract N00014-91-J-1334)
(AD-A260755) Avail: CASI HC A02/MF A01

Statistical signal processing functions such as signal detection, estimation, and identification play a key role in the development of effective communications, radar, and sonar systems. For example, advanced statistical methods are emerging as being particularly important in digital communications systems operating in channels corrupted by interference from such phenomena as multiple-access noise, intentional jamming, and impulsive noise sources. Conventional demodulation methods, such as coherent matched filtering, often suffer serious performance degradation when subjected to interference of these types; however, this degradation can frequently be eliminated through the use of more sophisticated signal processing techniques. A central issue in the design of effective signal processing procedures for systems operating in channels such as those noted above is that of channel identification. DTIC

AN INTRODUCTION TO DOPPLER EFFECT AND FADING IN MOBILE COMMUNICATIONS M.S. Thesis
Abdon B. DePaula Dec. 1992 88 p
(AD-A260976) Avail: CASI HC A05/MF A01

In this research we present an introductory analysis of a complex aspect of mobile communications: Doppler effect is evaluated in both Ricean and Rayleigh channels. A noncoherent 2-FSK scheme is selected to evaluate the behavior of the system under very strong fading channel conditions. The analysis is conducted for the binary case due to the possibility of developing closed form solutions. Therefore, the approach is simplified avoiding long lasting simulations that may obscure the concepts. The probability of bit error for the 2-FSK case can also be used as an initial bound for a M-FSK scheme. Diversity is evaluated as a means of combating fading and Doppler effects. Error correcting codes, in the form of a convolutional codes, are also used and applied to both effects. DTIC

EXPERIMENTAL STUDY OF THE EFFECT OF HELICAL GROOVES ON AN INFINITE CYLINDER M.S. Thesis
Thomas D. Suart Dec. 1992 124 p
(AD-A260890) Avail: CASI HC A06/MF A02

A series of low-speed wind-tunnel investigations were conducted to determine the aerodynamic behavior of a grooved inclined cylinder representing a long trailing wire antenna towed from an orbiting airplane. The large angle-of-attack range of the trailing wire required two different model configurations. The first configuration, using full-scale wire lengths suspended between steel stanchions, was mounted on a flush four-degree-of-freedom wall balance. The second configuration used a 15-scale grooved cylinder model with an ogive nose mounted on a six-degree-of-freedom sting balance. Wall balance wire data, valid for higher angles of attack, were integrated with low angle-of-attack sting balance data. Empirical relationships for the normal and axial force coefficients were verified with historical references for tested clean circular cylinders and extended for the grooved configurations. Existence of a side force coefficient due to circulation caused by the helical grooves was discovered, expressed analytically, and verified with flow-visualization techniques. Finally, the experimental coefficients were used to improve an existing simulation model describing the static equilibrium conditions of a cable towed by an airplane in a circular orbit. Inclusion of the side force influence in the static model proved consistent with the lateral skew angle and direction observed during flight test. DTIC

(NASA-CR-192804; JPL-TDA-PR-42-109; NAS 1.26:192804) Avail: CASI HC A18/MF A04

This quarterly publication provides archival reports on developments in programs managed by JPL's Telecommunications and Data Acquisition (TDA) Office. In the Search for Extraterrestrial Intelligence (SETI), the TDA Progress Report reports on implementation and operations for searching the microwave spectrum. In solar system radar, it reports on the uses of the Goldstone Solar System Radar for scientific exploration of the planets, their rings and satellites, asteroids, and comets. In radio astronomy, the areas of support include spectroscopy, very long baseline interferometry, and astrometry. These three programs are performed for NASA's Office of Space Science and Applications (OSSA) with the Office of Space Operations for funding DSN operational support. For individual titles, see N93-26106 through N93-26130.

A DETERMINATION OF THE RADIO-PLANETARY FRAME TIE FROM COMPARISON OF EARTH ORIENTATION PARAMETERS
Mark Harold Finger (Computer Sciences Corp., Beltsville, MD.) and William M. Folkner *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 1-21 (For primary document see N93-26105 09-32)
(RTOP 310-10-60-50-00)
Avail: CASI HC A03/MF A04

The orientation of the reference frame of radio source catalogs relative to that of planetary ephemerides, or 'frame tie,' can be a major systematic error source for interplanetary spacecraft orbit determination. This work presents a method of determining the radio-planetary frame tie from a comparison of very long baseline interferometry (VLBI) and lunar laser ranging (LLR) station coordinate and Earth orientation parameter estimates. A frame tie result is presented with an accuracy of 25 nrad.

OCCULTATION OF A COMPACT RADIO SOURCE BY VENUS
R. Linfield *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 22-39 (For primary document see N93-26105 09-32)
(RTOP 310-10-60-60-00)
Avail: CASI HC A03/MF A04

An occultation of the compact radio source P 0507+17 by Venus on 19 July 1988, was observed in Tidbinbilla, Australia at a frequency of 2.3 GHz. The purpose of this observation was to measure the position of Venus in the radio reference frame. When data from both ingress (Venus day side) and egress (Venus nightside) were used to solve for the position of Venus in ecliptic longitude and latitude, the results were consistent with zero offsets from the nominal values, with an uncertainty of approximately 0.2 arcsec in both coordinates. By using the nightside data alone, a value of -0.026+/-0.04 arcsec was obtained for the linear combination delta(lamda) + 0.51delta(beta) where delta(lambda) and delta(beta) were the offsets from their nominal values of the ecliptic longitude and latitude of Venus. Distortion of a vacuum Fresnel fringe pattern by the Venus troposphere, and especially by the Venus ionosphere, was observed. The day side ionosphere of Venus caused very large distortions; the amplitude of the first Fresnel fringe in the ingress data was eight times larger than had been expected for an airless planet. The observed fringe patterns were modeled by using plausible ionospheres (i.e., consistent with spacecraft measurements of the Venus ionosphere and with solar extreme ultraviolet flux and solar wind pressure measurements at the occultation epoch). However, the range of Venus ionospheric profiles (electron density as a function of altitude) allowed by a priori constraints and by the occultation data was large (e.g., the ionopause height on the day side was uncertain by a factor of two). This ionospheric uncertainty (particularly on the day

side) translated into a large position uncertainty (0.2 arcsec for the day side and 0.04 arcsec for the nightside). If it had been possible to calibrate the Venus ionosphere by some external means, the accuracy in delta(lambda) and delta(beta) would have been 0.01 arcsec or better. Author (revised)

A NANORADIAN DIFFERENTIAL VLBI TRACKING DEMONSTRATION
R. N. Treuhaft and S. T. Lowe *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 40-55 (For primary document see N93-26105 09-32)
(RTOP 310-10-60-86-02)
Avail: CASI HC A03/MF A04

The shift due to Jovian gravitational deflection in the apparent angular position of the radio source P 0201+113 was measured with very long baseline interferometry (VLBI) to demonstrate a differential angular tracking technique with nanoradian accuracy. The ray path of the radio source P 0201+113 passed within 1 mrad of Jupiter (approximately 10 Jovian radii) on 21 Mar. 1988. Its angular position was measured 10 times over 4 hours on that date, with a similar measurement set on 2 Apr. 1988, to track the differential angular gravitational deflection of the ray path. According to general relativity, the expected gravitational bend of the ray path averaged over the duration of the March experiment was approximately 1.45 nrad projected onto the two California-Australia baselines over which it was measured. Measurement accuracies on the order of 0.78 nrad were obtained for each of the ten differential measurements. The Chi-squared per degree of freedom of the data for the hypothesis of general relativity was 0.6, which suggests that the modeled dominant errors due to system noise and tropospheric fluctuations fully accounted for the scatter in the measured angular deflections. The Chi-squared per degree of freedom for the hypothesis of no gravitational deflection by Jupiter was 4.1, which rejects the no-deflection hypothesis with greater than 99.999-percent confidence. The system noise contributed about 0.34 nrad per combined-baseline differential measurement and tropospheric fluctuations contributed about 0.70 nrad. Unmodeled errors were assessed, which could potentially increase the 0.78-nrad error by about 8 percent. The above Chi-squared values, which result from the full accounting of errors, suggest that the nanoradian gravitational deflection signature was successfully tracked.

DEEP-SPACE NAVIGATION WITH DIFFERENCED DATA TYPES. PART 3: AN EXPANDED INFORMATION CONTENT AND SENSITIVITY ANALYSIS **c17**
J. A. Estefan and S. W. Thurman *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 56-73 (For primary document see N93-26105 09-32)
(RTOP 310-10-63-50-00)
Avail: CASI HC A03/MF A04

An approximate six-parameter analytic model for Earth-based differenced range measurements is presented and is used to derive a representative analytic approximation for differenced Doppler measurements. The analytical models are tasked to investigate the ability of these data types to estimate spacecraft geocentric angular motion, Deep Space Network station oscillator (clock/frequency) offsets, and signal-path calibration errors over a period of a few days, in the presence of systematic station location and transmission media calibration errors. Quantitative results indicate that a few differenced Doppler plus ranging passes yield angular position estimates with a precision on the order of 0.1 to 0.4 microrad, and angular rate precision on the order of 10 to 25(10)(exp -12) rad/sec, assuming no a priori information on the coordinate parameters. Sensitivity analyses suggest that troposphere zenith delay calibration error is the dominant systematic error source in most of the tracking scenarios investigated; as expected, the differenced Doppler data were found to be much more sensitive to troposphere calibration errors than differenced range. By comparison, results computed using wide band and narrow band (delta)VLBI under similar circumstances yielded angular precisions of 0.07 to 0.4 /microrad, and angular rate precisions of 0.5 to 1.0(10)(exp -12) rad/sec. ORBITER-ORBITER AND ORBITER-LANDER TRACKING USING SAME-BEAM INTERFEROMETRY
William M. Folkner and J. S. Border *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 74-86 (For primary document see N93-26105 09-32)
(RTOP 310-10-63-88-01)
Avail: CASI HC A03/MF A04

Two spacecraft orbiting Mars will subtend a small angle as viewed from Earth. This angle will usually be smaller than the beam width of a single radio antenna. Thus the two spacecraft may be tracked simultaneously by a single Earth-based antenna. The same-beam interferometry (SBI) technique involves using two widely separated antennas, each observing the two spacecraft, to produce a measurement of the angular separation of the two spacecraft in the plane of the sky. The information content of SBI data is thus complementary to the line-of-sight information provided by conventional Doppler data. The inclusion of SBI data with the Doppler data in a joint orbit estimation procedure can desensitize the solution to gravity mismodeling and result in improved orbit determination accuracy. This article presents an overview of the SBI technique, a measurement error analysis, and an error covariance analysis of some examples of the application of SBI to orbit determination. For hypothetical scenarios involving the Mars Observer and the Russian Mars '94 spacecraft, orbit determination accuracy improvements of up to an order of magnitude are predicted, relative to the accuracy that can be obtained by using only Doppler data acquired separately from each spacecraft. Relative tracking between a Mars orbiter and a lander fixed on the surface of Mars is also studied. Results indicate that the lander location may be determined to a few meters, while the orbiter ephemeris may be determined with accuracy similar to the orbiter-orbiter case. Author

(RTOP 310-20-65-67-00)
Avail: CASI HC A03/MF A04

Laboratory test results of the initialization and tracking performance of an existing inertial-sensor-based instrument are given. The instrument, although not primarily designed for precision antenna pointing applications, demonstrated an on-average 10-hour tracking error of several millidegrees. The system-level instrument performance is shown by analysis to be sensor limited. Simulated instrument improvements show a tracking error of less than 1 mdeg, which would provide acceptable performance, i.e., low pointing loss, for the DSN 70-m antenna sub network, operating at Ka-band (1-cm wavelength). PERFORMANCE OF A 12-GHz FIBER-OPTIC SYSTEM FOR BEAM-WAVEGUIDE ANTENNA STABILITY TESTING **c74**
T. Y. Otoshi, M. M. Franco, and G. F. Lutes *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 105-113 (For primary document see N93-26105 09-32)
(RTOP 310-20-65-92-01)
Avail: CASI HC A02/MF A04

A 12-GHz fiber-optic system is a critical part of a test configuration that was proposed for measuring the fractional frequency stability of the

DSS-13 beamwaveguide (BWG) antenna. This fiber-optic system is used to carry Ku-band (12 GHz) signals from a reference antenna to the DSS-13 BWG pedestal room. Tests performed only on the fiber-optic system portion of the overall test configuration showed that the 12-GHz fiber-optic system (installed at DSS-13) has a frequency stability of about 1.1(10)(exp -16) for sampling time tau = 1000 sec for a nighttime run. This preliminary result establishes the lowest noise floor that can probably be achieved for the test configuration that will be used to measure the frequency stability of the DSS-13 BWG antenna. NOISE-OPTIMAL CONTROL OF HEMT LNA'S FOR COMPENSATION OF TEMPERATURE DEVIATIONS **c33**
C. MacCarley, J. J. Bautista, and P. A. Willis *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 121-129 (For primary document see N93-26105 09-32)
(RTOP 310-20-66-09-01)
Avail: CASI HC A02/MF A04

Noise-optimal control of high-electron mobility transistor low noise amplifier (HEMT LNA) bias voltage and current values was achieved at room temperature. The performance metric maximized was the amplifier gain divided by the amplifier input noise temperature, G/T(sub e). Additionally, the feasibility of automating the initial determination of bias settings was demonstrated in the laboratory. Simulation models of an HEMT were developed from available measurement data, installed on a Sun SPARC 1 workstation and used in investigating several optimization algorithms. Simple tracking-type algorithms, which follow changes in optimum settings if started at or near the global optimum point, produced the best performance. Implementation of the optimization algorithms was performed using a three-stage Field Effect Transistor (FET) LNA and an existing test apparatus. Software was written to control the bias settings of the first stage of the LNA and to perform noise and gain measurements by using the test apparatus. The optimization control was then integrated with existing test software to create a master test and optimization program for test apparatus use. Author (revised)

The (24,12;8) extended Golay Code can be generated as a 6x4 binary matrix from the (15,11;3) BCH-Hamming Code, represented as a 5 x 3 matrix, by adding a row and a column, both of odd or even parity. The odd-parity case provides the additional 12th dimension. Furthermore, any three columns and five rows of the 6 x 4 Golay form a BCH-Hamming (15,11;3) Code. Similarly a (80,58;8) code can be generated as a 10 x 8 binary matrix from the (63,57;3) BCH-Hamming Code represented as a 9 x 7 matrix by adding a row and a column both of odd and even parity. Furthermore, any seven columns along with the top nine rows is a BCH-Hamming (63,57;3) Code. A (80,40;16) 10 x 8 matrix binary code with weight structure identical to the extended (80,40;16) Quadratic Residue Code is generated from a (63,39;7) binary cyclic code represented as a 9 x 7 matrix, by adding a row and a column, both of odd or even parity. The capacity and sensitivity of a direct-detection optical channel are calculated and compared to those of a white Gaussian noise channel. Unlike Gaussian channels in which the receiver performance can be characterized using the noise temperature, the performance of the direct-detection channel depends on both signal and background noise, as well as the ratio of peak to average signal power. Because of the signal-power dependence of the optical channel, actual performance of the channel can be evaluated only by considering both transmit and receive ends of the systems. Given the background noise power and the modulation bandwidth, however, the theoretically optimum receiver sensitivity can be calculated. This optimum receiver sensitivity can be used to define the equivalent receiver noise temperature and calculate the corresponding G/T product. It should be pointed out, however, that the receiver sensitivity is a function of signal power, and care must be taken to avoid deriving erroneous projections of the direct-detection channel performance. OPTIMIZING THE G/T RATIO OF THE DSS-13 34-METER BEAM-WAVEGUIDE ANTENNA
M. S. Esquivel *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 152-161 (For primary document see N93-26105 09-32)
(RTOP 310-30-69-91-02)
Avail: CASI HC A02/MF A04

Calculations using Physical Optics computer software were done to optimize the gain-to-noise temperature (G/T) ratio of DSS-13, the DSN's 34-m beam-waveguide antenna, at X-band for operation with the ultra-low-noise amplifier maser system. A better G/T value was obtained by using a 24.2-dB far-field-gain smooth-wall dual-mode horn than by using the standard X-band 22.5-dB-gain corrugated horn. Author (revised)

DYNAMIC MODELING OF FLUID TRANSMISSION LINES OF THE DSN 70-METER ANTENNAS BY USING A LUMPED PARAMETER MODEL **c37**
R. D. Bartos *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 162-169 (For primary document see N93-26105 09-32)
(RTOP 310-30-42-10-87)
Avail: CASI HC A02/MF A04

Fluid transmission lines and fittings have been found to significantly affect the dynamic and steady state operation of the engineering system in which they are incorporated. Therefore, a better understanding of the operation of a system can be obtained by including the performance of the transmission lines and fittings within the system model. The most accurate model of a transmission line or fitting is obtained by using a distributed parameter model. However, a distributed parameter model tends to be very complex. This complexity can be avoided without significant loss of model accuracy by using a lumped parameter model when the length of the fluid path through the transmission line or fitting is short. This article develops a lumped parameter model for short fluid transmission lines and fittings, describes the conditions under which the model is valid, and presents the model parameters associated with the servo hydraulic system of the Deep Space Network (DSN) 70-meter antennas. (RTOP 310-30-71-92-02)
Avail: CASI HC A02/MF A04

This article discusses a method for downconverting the square-wave subcarrier of spacecraft signals, such as the one from Galileo, which results in a compression bandwidth that lowers the sample rate significantly. The study is focused on three issues. The first is the selection of an adequate down-mixing signal for the resulting signal to have a format similar to that of the original signal, except at a lowersub carrier frequency. The second is the control of the noise level so that the signal to noise ratio is not degraded due to the downconversion. The third is to determine the bandwidth of the downconverted signal considering the uncertainty of the residual carrier frequency. Author

DSS-13 26-METER ANTENNA UPGRADED RADIOMETER SYSTEM
C. T. Stelzried, L. Skjerve, and G. Bury *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 209-220 (For primary document see N93-26105 09-32)
(RTOP 314-40-31-30-06)
Avail: CASI HC A03/MF A04

The DSS-13 26-m antenna radiometer system was upgraded with an IBM compatible computer-controlled configuration with improved supporting hardware and software. Software was generated to analyze results and correct for antenna mispointing, tropospheric loss, and other observing errors. This total power radiometer configuration provides a prototype for the new DSS-13 34-m antenna. The radiometer system is described in terms of the theory, instrumentation hardware, computer configuration, and operational features and performance. The system is used to obtain antenna efficiency and pointing model data and is useful for radio source calibrations required for radio astronomy. Some recent results are given.

SEQUENTIAL DESIGN OF A LINEAR QUADRATIC CONTROLLER FOR THE DEEP SPACE NETWORK ANTENNAS
W. Gawronski *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 221-252 (For primary document see N93-26105 09-32)
(RTOP 314-40-41-10-15)
Avail: CASI HC A03/MF A04

A new linear quadratic controller design procedure is proposed for the NASA/JPL Deep Space Network antennas. The antenna model is divided into a tracking subsystem and a flexible subsystem. Controllers for the flexible and tracking parts are designed separately by adjusting the performance index weights. Ad hoc weights are chosen for the tracking part of the controller and the weights of the flexible part are adjusted. Next, the gains of the tracking part are determined, followed by the flexible controller final tune-up. In addition, the controller for the flexible part is designed separately for each mode; thus the design procedure consists of weight adjustment for small-size subsystems. Since the controller gains are obtained by adjusting the performance index weights, determination of the weight effect on system performance is a crucial task. A method of determining this effect that allows an on-line improvement of the tracking performance is presented in this article. The procedure is illustrated with the control system design for the DSS-13 antenna. Author

The Magellan Project levied the stringent requirement of a 98-percent high-rate telemetry data capture rate on the Deep Space Network (DSN) during the Magellan Prime Mapping Mission. To meet this requirement, the DSN undertook extensive development of the DSN Telemetry System, as well as extensive DSN operations planning and test and training. In actuality, the DSN substantially exceeded the requirement by achieving a Prime Mapping Mission high-rate telemetry data capture rate of 99.14 percent. This article details the DSN telemetry system development and DSN operations planning and test and training. In addition, the actual high-rate telemetry data outages are comprehensively presented and analyzed.

DEEP SPACE NETWORK INFORMATION SYSTEM ARCHITECTURE STUDY **c82**
C. A. Beswick, R. W. Markley, ed., D. J. Atkinson, L. P. Cooper, R. C. Tausworthe, R. C. Masline, J. S. Jenkins, R. A. Crowe, J. L. Thomas, and M. J. Stoloff *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 282-355 (For primary document see N93-26105 09-32)
(RTOP 314-30-58-50-05)
Avail: CASI HC A04/MF A04

The purpose of this article is to describe an architecture for the DSN information system in the years 2000-2010 and to provide guidelines for its evolution during the 1990's. The study scope is defined to be from the front-end areas at the antennas to the end users (spacecraft teams, principal investigators, archival storage systems, and non-NASA partners). The architectural vision provides guidance for major DSN implementation efforts during the next decade. A strong motivation for the study is an expected dramatic improvement in information-systems technologies--i.e., computer processing, automation technology (including knowledge-based systems), networking and data transport, software and hardware engineering, and human-interface technology. The proposed Ground Information System has the following major features: unified architecture from the front-end area to the end user; open-systems standards to achieve interoperability; DSN production of level 0 data; delivery of level 0 data from the Deep Space Communications Complex, if desired; dedicated telemetry processors for each receiver; security against unauthorized access and errors; and highly automated monitor and control. GENERALIZED PROBABILITY MODEL FOR CALCULATION OF INTERFERENCE TO THE DEEP SPACE NETWORK DUE TO CIRCULARLY EARTH-ORBITING SATELLITES
C. J. Ruggier *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 356-366 (For primary document see N93-26105 09-32)
(RTOP 315-20-50-00-06)
Avail: CASI HC A03/MF A04

The probability of exceeding interference power levels and the duration of interference at the Deep Space Network (DSN) antenna is calculated parametrically when the state vector of an Earth-orbiting satellite over the DSN station view area is not known. A conditional probability distribution function is derived, transformed, and then convolved with the interference signal uncertainties to yield the probability distribution of interference at any given instant during the orbiter's mission period. The analysis is applicable to orbiting satellites having circular orbits with known altitude and inclination angle. Author (revised)

Ka-BAND FEED ARRAYS FOR SPACECRAFT REFLECTOR ANTENNAS WITH LIMITED SCAN CAPABILITY: AN OVERVIEW
V. Jamnejad *In its* The Telecommunications and Data Acquisition Report 15 May 1992 p 367-376 (For primary document see N93-26105 09-32)
(RTOP 315-91-50-20-04)
Avail: CASI HC A02/MF A04

The Jet Propulsion Laboratory (JPL) and NASA are in the process of developing ground and spacecraft antenna systems at Ka-band frequencies for future deep space applications. The use of Ka-band (32-GHz down) communication will result in smaller ground and spacecraft antennas and associated equipment and will provide the larger bandwidths necessary for very high data rate communication and radio navigation. In this article, the use of a small phased array as a feed for a reflector antenna system with limited scan capability is addressed. Different feed and antenna configurations, as well as array architectures, are examined. Some theoretical and experimental parameters of a particular breadboard feed array developed by JPL and the University of Massachusetts are presented. Guidelines for the future direction of this effort are provided. Author (revised)

PROOF OF FAULT COVERAGE FOR A FORMAL PROTOCOL TEST PROCEDURE M.S. Thesis
Michael A. Randall Dec. 1992 57 p
(AD-A261612) Avail: CASI HC A04/MF A01

Due to the speed and complexity of communication networks being designed today, it is imperative to ensure that they operate correctly. Todays fiber optic networks, which can transmit billions of bits per second over thousands of miles, are heavily dependent on sophisticated software and protocols which are becoming increasingly difficult to test. Conformance testing is a method that is used for this purpose: to test the design of a protocol against an implementation of the design. This thesis provides some insight into the conformance testing problem by first providing background on some current protocol test methods and then focusing on a newer method, which is based on a formal protocol specification. A proof is given that demonstrates the method's error detection capabilities. Two well known local area network protocols, Token Bus and Fiber Distributed Data Interface (FDDI), are used as examples to illustrate how the test method is applied to a specification. DTIC

REALTIME CONTROL OF MULTIPLE SENSOR SYSTEMS Final Report
Gilmer Blankenship, Charles Fletcher, and Anthony LaVigna 29 Jan. 1993 48 p
(Contract DAAL03-92-C-0025)
(AD-A261037; TSI-ARO-93-1) Avail: CASI HC A03/MF A01

The technical objectives of this project are the design and demonstration of methods for the optimal management of sensor systems. As a specific application, we consider the nonlinear filtering of a vector diffusion process, with several noisy vector observations. Any number of sensors can be utilized in the signal processing performed by the nonlinear filter. The problem considered is the optimal selection of a schedule of these sensors from the available set, so as to optimally estimate a function of the state at some given time. Solution of the optimal schedule is derived from solving a system of quasi-linear inequalities (QVI's). The schedule derived from these methods is optimal with respect to predetermined, but possibly varying, running and switching costs for the sensors, as well as some cost functional of the estimate of the dynamics. Methods include precise strategies for adapting the sensor configuration to the engagement at hand, including optimal timing of decisions to communicate or activate active sensors which reveal position. These strategies have been developed by TSI in the form of feedback control laws which are computationally efficient and simple to implement. DTIC

ADMISSION CONTROL IN INTEGRATED VOICE/DATA MULTIHOP RADIO NETWORKS Interim Report, Dec. 1991 - Dec. 1992
Craig M. Barnhart, Jeffrey E. Wieselthier, and Anthony Ephremides 18 Jan. 1993 54 p
(Proj. RR0-1509)
(AD-A261055; NRL/MR/5521-93-7196) Avail: CASI HC A04/MF A01

In this report, we investigate the admission control problem for voice traffic in integrated multihop radio networks. We consider only those admission control policies that yield a 'coordinate convex' state space. This restriction, in conjunction with the use of a 'blocked-calls-cleared' mode of operation and the assumption that the voice process is Markovian, results in a product-form stationary distribution for the voice state of the system. The product-form distribution allows the straightforward evaluation of network performance when subject to different admission control policies. A large number of coordinate convex admission-control policies must be searched to determine the optimal policy. We develop a recursive procedure to speed the evaluation of a large number of different policies, as well as descent-search method to reduce significantly the number of policies that must be evaluated in searching for the optimal one. The numerical examples we present indicate that improved performance can be obtained by administering admission control, but this improvement is typically small unless different revenues or costs are associated with the various call types. NEW ALGORITHMS FOR THE DETECTION AND ELIMINATION OF SINE WAVES AND OTHER NARROW-BAND SIGNALS IN THE PRESENCE OF BROADBAND SIGNALS AND NOISE
Michael A. Soderstrand, K. V. Rangarao, and H. H. Loomis 1 Oct. 1992 80 p Sponsored in part by AF
(AD-A261811; NPS-EC-93-005) Avail: CASI HC A05/MF A01

Four different classes of adaptive signal cancelers can be used to eliminate narrow-band interference from a broadband signal: (1) cascaded second-order notch filters; (2) high-order in-line notch filters; (3) second-order bandpass noise cancelers; and (4) high-order bandpass noise cancelers. Of the four, a structure based on second-order bandpass filters used as signal cancelers is found to perform better than the other structures. An adaptive algorithm for these filters has been proposed. The structure can be reduced in hardware complexity without degrading performance using a new adaptive algorithm that out-performs any of the other known structures or algorithms. This new structure is particularly suited to the elimination of narrow-band interference in broadband Bi-Phase Shift-Key (BPSK) signals with and without background noise. DTIC

SPECIAL TECHNOLOGY AREA REVIEW ON MICROWAVE PACKAGING TECHNOLOGY
Becky Terry Feb. 1993 41 p Sponsored by DOD
(AD-A261852) Avail: CASI HC A03/MF A01

Microwave (MW) and millimeter wave (MMW) multichip module (MCM) packaging is an emerging technology that is of great importance for both defense and commercial applications. Military applications such as radar, electronic warfare, communications, and smart munitions and commercial applications such as communications, direct broadcast satellite, cellular telephone, and automotive electronics all require MW and/or MMW electronics. The spectrum of needs ranges from low volume, high performance electronics to high volume, low cost applications. A significant aspect of realizing these components and systems will be the development of a broad range of packaging and interconnect technologies that have the required reliability and environmental protection and are affordable and applicable to both the military and commercial sectors. HIGH FREQUENCY (HF) RADIOWAVE PROPAGATION
Gary S. Sales Apr. 1992 38 p
(Contract F19628-90-K-0029)
(AD-A261726; PL-TR-92-2123; AD-E201407; SR-6) Avail: CASI HC A03/MF A01

This report serves to introduce the basics of high frequency radiowave propagation in the earth's ionosphere. It is intended for people who are not fully acquainted with the physics of the problem but have had some experience working with or will have to work with over-the-horizon radar systems. This material, after an introduction to propagation theory and terminology, concentrates on the features of the OTH radar. First, backscatter ionogram is introduced as the primary diagnostic tool for the management of the radar in terms of the ionospheric environment. The synthesis of these ionograms is presented in detail as a way of leading to a better understanding of HF radiowave propagation. Special emphasis is placed on a description of the effects of ionospheric clutter and sporadic-E on the performance of the radar. DTIC

STATISTICS OF SAMPLED RICIAN FADING Technical Report, 1 Jan. - 31 Jun. 1992
Roger A. Dana 1 Feb. 1993 61 p
(Contract DNA001-91-C-0010)
(AD-A261397; MRC-R-1410; DNA-TR-92-98) Avail: CASI HC A04/MF A01

Realizations of the channel impulse response function generated with Rician amplitude statistics have been used for many years to evaluate system performance in the regime between full Rayleigh fading and ambient non-fading conditions. While it is well known that Rician distributed realizations fail to match observed phase fluctuations, Rician statistics provide a worst case description of the occurrence of deep fades. Thus the use of Rician statistics is attractive in slow fading situations where system performance has been rendered insensitive to phase variations. The purposes of this report are to provide new information on the temporal statistics of Rician fading (mean fade duration and separation) and to determine sampling requirements on realizations of the channel impulse response function with Rician amplitude statistics. It is found that 400 decorrelation time (tau(sub 0)) realizations generated with 10 samples per tau(sub 0) and sampled at tau(sub 0)/40 accurately reproduce the temporal statistics of Rician fading. IMPLEMENTATION OF CYCLIC SPECTRAL ANALYSIS METHODS M.S. Thesis
Nancy J. Carter Dec. 1992 112 p
(AD-A261715) Avail: CASI HC A06/MF A02

Phase-shift keyed (PSK) signal modulation methods are coming into increasing use in modem communications. This thesis describes the implementation of three methods of computing the cyclic spectrum to determine the presence of PSK signals. The Strip Spectral Correlation Algorithm (SSCA) and the Fast Fourier Transform (FFT) Accumulation Method (FAM) both estimate the cyclic spectral plane. The Sub-FFT Accumulation Method (SUBFAM) program computes the Spectral Correlation Function (SCF) for a set of possible spectral frequencies for a single cycle frequency. The results of algorithm performance are presented along with a discussion of promising areas for performance enhancement and automation of signal detection and classification. DTIC

MICROSTRIP ANTENNAS ON/IN ANISOTROPIC MATERIAL LAYERS Final Report, Aug. 1988 - Feb. 1991
Hung-Yu Yang, Jesse A. Castaneda, and Akifumi Nakatani Nov. 1992 97 p
(Contract F19628-88-C-0059)
(AD-A261700; RPT-91025; RL-TR-92-257) Avail: CASI HC A05/MF A02

Accurate fullwave analyses of microstrip dipoles on multi-layer substrates with generalized anisotropic permittivity and permeability have been developed. The solution to the problem of microstrip dipoles on/in gyrotropic substrates has been obtained. The potential of electronically shaped, scanned, and gain enhanced element factors with ferrite substrates has been theoretically demonstrated. The scattering and radiation problems were solved. The use of biased ferrite substrates to simultaneously reduce

RCS and preserve antenna in-band gain has also been described. Infinite phased arrays of microstrip dipoles and probe-fed patches on general anisotropic multi-layer substrates have been analyzed. All the solutions involve the dyadic Green's function for the anisotropic layered structure and the application of the method of moments to an electric field integral equation. DTIC

THE DESIGN AND EVALUATION OF TRANSMIT AND RECEIVE ANTENNAS FOR AN IONOSPHERIC COMMUNICATIONS PROBE SYSTEM. B: SLOPING-VEE BEAMS M.S. Thesis
Georgios T. Bougioukos Dec. 1992 112 p
(AD-A261866) Avail: CASI HC A06/MF A02

The purpose of this study was to design and evaluate the performance of a transmitting antenna for an HF communications probe system. Monterey, CA, was selected as the transmit site, and San Diego, CA, was selected as the receive site to establish an ionospheric communication link to test the equipment involved in the probe system. A sloping-vee antenna was chosen for initial shakedown tests to support the transmitting requirements of the probe system at 5.6, 11, and 16.8 MHz. The Eyring Ground Measurement Probe was used to measure the ground constants at the NPS beach site. The Numerical Electromagnetics Code (NEC) was utilized to analyze the performance of the antenna at the NPS beach, and for average, poor, fair and arctic ground conditions. The antenna provides a maximum gain of 1.46 dBi at 5.6 MHz, 5.56 dBi at 11 MHz, 8 dBi at 16.8 MHz, and positive gain at take-off angles between 3 deg and 33 deg at frequencies from 5.6 to 16.8 MHz. The VSWRs with a standard 600 Ohm to 50 Ohm impedance matching transformer (12:1) are 1.73 at 5.6 MHz, 1.77 at 11 MHz, and 1.53 at 16.8 MHz. DTIC

TRELLIS CODED CPFSK M.S. Thesis
Zafer Inceoglu 10 Dec. 1992 55 p
(AD-A261788) Avail: CASI HC A04/MF A01

Continuous Phase Frequency Shift Keying (CPFSK) is a potentially attractive modulation scheme with constant envelope and good spectral characteristics for energy constrained and band-limited satellite channels. This research deals with Orthogonal Frequency Shift Keying (FSK), Minimum Shift Keying (MSK) which is a special case of CPFSK, uncoded quaternary CPFSK, and finally coded quaternary CPFSK. Orthogonal FSK is simulated by making the modulation index (h) equal to one, and all of the other simulations are performed with h=1/2. A rate 1/2 convolutional encoder with constraint lengths (k), k=2, 3, and 4 are used in coded quaternary CPFSK simulations. Good coding gains are obtained with only a slight increase in receiver complexity. Soft decision with the Viterbi Algorithm was applied to all CPFSK and one MSK application. Hard decision was applied to Orthogonal FSK and another MSK application. DTIC

NEW RESULTS IN SIGNAL DESIGN FOR THE AWGN CHANNEL
Michael J. Steiner 31 Jan. 1993 27 p
(AD-A261424; NRL/FR/5341-93-9524) Avail: CASI HC A03/MF A01

The design of M average power constrained signals in white Gaussian noise (AWGN) is addressed. The long-standing strong simplex conjecture which postulates that the optimal signals, under an average power constraint, are the vertices of a regular simplex, is disproven. A signal set is shown that performs better than the regular simplex at low signal-to-noise ratios for an M greater than or equal to 7. This leads to a theorem stating that for any fixed M greater than or equal to 7 no signal set exists that is optimal at all signal-to-noise ratios. Furthermore it is found that the optimal solution at low signal-to-noise ratios is not an equal energy solution for any M greater than or equal to 7. The regular simplex is shown to be the unique polytope that maximizes the minimum distance between signals. This result leads to the corollary that a signal set which maximizes the minimum distance is not necessarily optimum. However, the regular simplex is shown to be globally optimum in the sense of uniquely maximizing the union bound at all signal-to-noise ratios. DTIC

RADAR SENSING OF PETROLEUM SEEPAGE GASES Final Report
Donald F. Hemenway, James P. Hansen, and Eugene G. George 17 Jan. 1993 62 p
(AD-A261431; NRL/MR/5300-93-7177) Avail: CASI HC A04/MF A01

Simple X-band radars have been used by a number of commercial exploration companies since 1972 in the search for gas and oil deposits. Uncertainty and controversy over the physical mechanism involved in the radar sensing of gas and oil led to the April/May 1992 radar investigation conducted by NRL. A low power X-band radar was used by NRL to acquire experimental data in Texas. The attributes of return signals observed over producing and prospective oil fields were found to have a unique set of characteristics which included the following: return signals were from weak, distributed targets: simultaneous amplitude and range variations were observed (10 dB or more in amplitude and +/- 60 ft in range) within time intervals of 1/3rd second and at ranges of from 500 to 2,000 ft, and at elevation angles of less than + 1 deg. The range and amplitude varying radar returns were suppressed by rain and/or a wet earth. Also during a single period of 24 hour observation, the varying signals disappeared during a period of high humidity (local night-time) and then re-appeared the next day when the relative humidity dropped below 50%. Radar returns from seepage gases heights greater than 25 feet as well as gas associated radar returns over cattle feed lots (methane and ammonia) were not confirmed. DTIC

PROCEEDINGS OF THE 16TH NASA PROPAGATION EXPERIMENTERS MEETING (NAPEX 16) AND THE ADVANCED COMMUNICATIONS TECHNOLOGY SATELLITE (ACTS) PROPAGATION STUDIES MINIWORKSHOP
Faramaz Davarian, ed. 1 Aug. 1992 254 p Meeting and workshop held in Houston, TX, 29-30 May 1992
(Contract NAS7-918)
(NASA-CR-192800; NAS 1.26:192800; JPL-Publ-92-16) Avail: CASI HC A12/MF A03

The NASA Propagation Experimenters Meeting (NAPEX), supported by the NASA Propagation Program, is convened annually to discuss studies made on radio wave propagation by investigators from domestic and international organizations. NAPEX 16 was held on May 29, 1992 in Houston, Texas. The meeting was organized into two technical sessions. The first session was dedicated to slant path propagation studies and measurements. The second session focused on Olympus propagation measurements and results. Following NAPEX 16, the Advanced Communications Technology Satellite (ACTS) Miniworkshop was held to review ACTS propagation activities with emphasis on ACTS hardware development and experiment planning. Eight technical papers were presented by contributors from government agencies, private industry, and university research establishments. For individual titles, see N93-26464 through N93-26486.

OPENING REMARKS
Faramaz Davarian *In its* Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 4-7 (For primary document see N93-26463 09-32)
Avail: CASI HC A01/MF A03

The year's accomplishments at the onset of the yearly NAPEX meetings are reviewed. Therefore, I will present the last year's accomplishments and the plans for the next year. The studies supported by the Propagation Program during the last year are listed: OLYMPUS data collection and analysis; the ACTS Propagation Program; low elevation angle 11-GHz measurements; satellite broadcast and mobile studies; radiometric

techniques; propagation models database; NASA Reference Publication 1274; CCIR activities; fade detection and compensation; rain rate measurements; and information dissemination. Author (revised)

THE ACTS PROPAGATION PROGRAM
D. Chakraborty and Faramaz Davarian *In its* Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 13-16 (For primary document see N93-26463 09-32)
Avail: CASI HC A01/MF A03

The success or failure of the ACTS experiment will depend on how accurately the rain-fade statistics and fade dynamics can be predicted in order to derive an appropriate algorithm that will combat weather vagaries, specifically for links with small terminals, such as very small aperture terminals (VSAT's) where the power margin is a premium. The planning process and hardware development program that will comply with the recommendations of the ACTS propagation study groups are described. Author (revised)

From the NOAA 15 minute precipitation file for the U.S., data was selected for 128 stations covering a 17 year period and the probability of simultaneous rainfall at several stations was calculated. We assumed that the chosen stations were located in separate beams of a multi-beam communications satellite with shared fade mitigation resources. In order to estimate the demands made on these resources, we determined the number of stations at which rainfall rates exceeded 10 to 40 mm/hr. We found a 1 percent probability that at least 5 of the 128 stations have rain at or over 10 mm/hr in any 15 minute interval. Rain at 2 stations was found to correlate over distances less than about 600 miles. Author (revised)

L- AND K-BAND LMSS PROPAGATION MEASUREMENTS USING MARECS-B, OLYMPUS, AND ACTS
W. J. Vogel, G. W. Torrence, J. Goldhirsh (Johns Hopkins Univ., Laurel, MD.), and J. R. Rowland (Johns Hopkins Univ., Laurel, MD.) *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 27-33 (For primary document see N93-26463 09-32)
Avail: CASI HC A02/MF A03

L-band measurements of land mobile satellite systems (LMSS) propagation effects were last made at the end of 1988, but some voids were left in the database, making modeling of low elevation roadside tree shadowing and multipath reflections difficult for some path geometries. Transmission of a pilot tone from MARECS-B at 55 deg West during Sep. and Dec. 1991 gave an opportunity to fill the gaps in the experimental results. Two campaigns during which fade data were obtained at elevation angles from 7 deg to 40 deg are described. Below 15 deg, specular terrain reflections in a non-shadowing, hilly environment were observed to introduce significant fading. Although the reflecting surface was at a distance of up to several km, it is shown that the reflected signals are delayed by less than 1 microsec. Mobile measurements were also attempted receiving the 20 GHz Olympus beacon, but antenna pointing problems restricted first results to straight-line driving. Author (revised)

RAIN RATE AND MODELED FADE DISTRIBUTIONS AT 20 GHz AND 30 GHz DERIVED FROM FIVE YEARS OF NETWORK RAIN GAUGE MEASUREMENTS
Julius Goldhirsh, Vladimir Krichevsky (Micromat Research, Gaithersburg, MD.), and Norman Gebo *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 34-44 (For primary document see N93-26463 09-32)
(Contract N00039-91-C-0001)
Avail: CASI HC A03/MF A03

Five years of rain rate and modeled slant path attenuation distributions at 20 GHz and 30 GHz derived from a network of 10 tipping bucket rain gages was examined. The rain gage network is located within a grid 70 km north-south and 47 km east-west in the Mid-Atlantic coast of the United States in the vicinity of Wallops Island, Virginia. Distributions were derived from the variable integration time data and from one minute averages. It was demonstrated that for realistic fade margins, the variable integration time results are adequate to estimate slant path attenuations at frequencies above 20 GHz using models which require one minute averages. An accurate empirical formula was developed to convert the variable integration time rain rates to one minute averages. Fade distributions at 20 GHz and 30 GHz were derived employing Crane's Global model because it was demonstrated to exhibit excellent accuracy with measured COMSTAR fades at 28.56 GHz. Author

SATELLITE COMMUNICATIONS APPLICATION TO PACIFIC COUNTRIES ABOVE Ku BAND
Takashi Iida *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 70-75 (For primary document see N93-26463 09-32)
(Grant NAGw-1105)
Avail: CASI HC A02/MF A03

An application of satellite communications above the Ku band to the Pacific region is described, focusing on: (1) Lightsat system and (2) a high capacity satellite system. A small geostationary satellite system using Ku band for the Federated States of Micronesia is shown as an example. A concept of multi-gigabits/second high capacity communications system using

two satellites in the Ka band is described. The onboard bit-by-bit processing is very useful in the low link margin environment due to rain attenuation. These topics were obtained by the Asia Pacific Telecommunications Study granted by NASA conducted by the University of Colorado at Boulder.

A DATABASE FOR PROPAGATION MODELS
Anil V. Kantak and Krisjani S. Suwitra *In its* Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 76-80 (For primary document see N93-26463 09-32)
Avail: CASI HC A01/MF A03

In June 1991, a paper at the fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) was presented outlining the development of a database for propagation models. The database is designed to allow the scientists and experimenters in the propagation field to process their data through any known and accepted propagation model. The architecture of the database also incorporates the possibility of changing the standard models in the database to fit the scientist's or the experimenter's needs. The database not only provides powerful software to process the data generated by the experiments, but is also a time- and energy-saving tool for plotting results, generating tables, and producing impressive and crisp hard copy for presentation and filing. BRIGHTNESS TEMPERATURE AND ATTENUATION DIVERSITY STATISTICS AT 20.6 AND 31.65 GHz FOR THE COLORADO RESEARCH NETWORK
Ed R. Westwater, M. J. Falls, and E. Fionda (Fondazione Ugo Bordoni, Rome, Italy.) *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 81-96 (For primary document see N93-26463 09-32)
Avail: CASI HC A03/MF A03

A limited network of four dual-channel microwave radiometers, with frequencies of 20.6 and 31.65 GHz, was operated in the front range of eastern Colorado from 1985 to 1988. Data, from November 1987 through October 1988 are analyzed to determine both single-station and joint-station brightness temperature and attenuation statistics. Only zenith observations were made. The spatial separations of the stations varied from 50 km to 190 km. Before the statistics were developed, the data were screened by rigorous quality control methods. One such method, that of 20.6 vs. 31.65 GHz scatter plots, is analyzed in detail, and comparisons are made of measured vs calculated data. At 20.6 and 31.65 GHz, vertical attenuations of 5 and 8 dB are exceeded 0.01 percent of the time. For these four stations and at the same 0.01 percent level, diversity gains from 6 to 8 dB are possible with the 50 to 190 km separations. Author (revised)

A PROPOSED STUDY OF MULTIPLE SCATTERING THROUGH CLOUDS UP TO 1 THz
G. C. Gerace and E. K. Smith *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 97-115 (For primary document see N93-26463 09-32)
Avail: CASI HC A03/MF A03

A rigorous computation of the electromagnetic field scattered from an atmospheric liquid water cloud is proposed. The recent development of a fast recursive algorithm (Chew algorithm) for computing the fields scattered from numerous scatterers now makes a rigorous computation feasible. A method is presented for adapting this algorithm to a general case where there are an extremely large number of scatterers. It is also proposed to extend a new binary PAM channel coding technique (El-Khamy coding) to multiple levels with non-square pulse shapes. The Chew algorithm can be used to compute the transfer function of a cloud channel. Then the transfer function can be used to design an optimum El-Khamy code. In principle, these concepts can be applied directly to the realistic case of a time-varying cloud (adaptive channel coding and adaptive equalization). A brief review is included of some preliminary work on cloud dispersive effects on digital communication signals and on cloud liquid water spectra and correlations.

The World Administrative Radio Conference of 1992 (WARC 92) was held in Torremolinos, Spain, 3 Feb. - 3 Mar. 1992. Major topics considered included shortwave broadcasting, mobile and mobile-satellite service, broadcasting satellite service (sound and HDTV), space services above 20 GHz, and space research. Considerable attention was given to the congested 1-3 GHz band in general and to Low Earth Orbit (LEO) Mobile-Satellite Service, including 'little' LEO's operating below 1 GHz and to 'big' LEO's operating above 1 GHz. Significant new allocations were made for generic Mobile-Satellite Services (MSS). Proposals for allocations for uplink power control beacons and for space research received favorable treatment.

ESA'S PLANNING AND COORDINATION OF THE OLYMPUS PROPAGATION EXPERIMENT
B. Arbesser-Rastburg *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 131-142 (For primary document see N93-26463 09-32)
Avail: CASI HC A03/MF A03

An overview of the organization of the OLYMPUS propagation experimenters group (OPEX) is given. Preparations, participation, and experiments are described. Some examples for first statistical results are also reported. OLYMPUS, a 3-axis stabilized communications satellite was launched in 1989 for providing experimental telecommunications payloads and a propagation beacon payload at 12, 20, and 30 GHz to the European Space Agency. From previous experience (OTS), the Agency undertook to carry out extensive preparations with an eye on obtaining the statistical results needed within the limited available lifetime of the spacecraft. The OLYMPUS propagation experiment was conceived as part of ESA's space telecommunications applications program (ESA/IPC/(79)83) with the emphasis on exploring the possibilities and limitations of Ka-band satellite communications. The objectives of the OLYMPUS propagation campaign were: (1) characterization of the slant-path propagation conditions at 20/30 GHz in the various climatic regions of Europe; (2) improvement of the understanding of the link between atmospheric observable (rain rate, cloud thickness, etc.) to propagation impairments such as attenuation, depolarization, scintillation, etc.; and (3) arrive at improved propagation prediction methods. STATUS OF THE OLYMPUS EXPERIMENT AT CRC
David V. Rogers *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 166-170 (For primary document see N93-26463 09-32)
Avail: CASI HC A01/MF A03

The status of the Olympus Propagation Experiment of the Communications Research Centre in Ottawa, Canada, is briefly summarized. Path attenuation measurements at multiple frequencies correlated with concurrent dual polarized radar data provide a unique method to investigate propagation effects. An experiment of this type is being implemented by the Communications Research Centre (CRC) on the grounds of the National Research Council of Canada in Ottawa. Beacon receivers monitor signals from the Olympus satellite at 12.5, 19.77, and 29.66 GHz at a path elevation angle of 14.2 deg. Sky noise radiometers operating near the same frequencies and pointed along the same path provide additional propagation information. A colocated dual-polarized 9.6-GHz radar probes the precipitation state on the path, permitting identification of precipitation regimes that cause the observed impairments. The Olympus experiment configuration is displayed pictorially. Information on path propagation phenomena can be deduced by correlating the radar, beacon, and sky noise data. Melting layer effects and propagation losses for higher time percentages are prime interests. Data collected by Diversitel Communications during equipment verification tests are presented. A COMPARATIVE ASSESSMENT OF R. M. YOUNG AND TIPPING BUCKET RAIN GAUGES **c47**
Julius Goldhirsh and Norman E. Gebo *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 204-216 (For primary document see N93-26463 09-32)
(Contract N00039-91-C-0001)
Avail: CASI HC A03/MF A03

Rain rates as derived from standard tipping bucket rain gauges have variable integration times corresponding to the interval between bucket tips. For example, the integration time for the Weathertronics rain gauge is given by delta(T) = 15.24/R (min), where R is the rain rate expressed in mm/h and delta(T) is the time between tips expressed in minutes. It is apparent that a rain rate of 1 mm/h has an integration time in excess of 15 minutes. Rain rates larger than 15.24 mm/h will have integration times smaller than 1 minute. The integration time is dictated by the time it takes to fill a small tipping bucket where each tip gives rise to 0.254 mm of rainfall. Hence, a uniform rain rate of 1 mm/h over a 15 minute period will give rise to the same rain rate as 0 mm/h rainfall over the first 14 minutes and 15 mm/h between 14 to 15 minutes from the reference tip. Hence, the rain intensity fluctuations may not be captured with the tipping bucket rain gauge for highly variable rates encompassing lower and higher values over a given integration time. The objective of this effort is to provide an assessment of the features of the R. M. Young capacitive gauge and to compare these features with those of the standard tipping bucket rain gauge. A number of rain rate-time series derived from measurements with approximately co-located gauges are examined.

MORE RAIN COMPENSATION RESULTS
D. D. Sworder and R. Vojak *In* JPL, Proceedings of the 16th NASA Propagation Experimenters Meeting (NAPEX 16) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1992 p 235-244 (For primary document see N93-26463 09-32)
Avail: CASI HC A02/MF A03

To reduce the impact of rain-induced attenuation in the 20/30 GHz band, the attenuation at a specified signal frequency must be estimated and extrapolated forward in time on the basis of a noisy beacon measurement. Several studies have used model based procedures for solving this problem in statistical inference. Perhaps the most widely used model-based paradigm leads to the Kalman filter and its lineal variants. In this formulation, the dynamic features of the attenuation are represented by a state process (x(sub t)). The observation process (y(sub t)) is derived from beacon measurements. Some ideas relating to the signal processing problems related to uplink power control are presented. It is shown that some easily implemented algorithms hold promise for use in estimating rain induced fades. The algorithms were applied to actual data generated at the Virginia Polytechnic Institute and State University (VPI) test facility. Because only one such event was studied, it is not clear that the algorithms will have the same effectiveness when a wide range of events are studied. Derived from text

This research examines the interaction of acoustic and lexical information in the identification of words in lexically ambiguous phoneme sequences. In Experiment 1, subjects show priming for the meaning of a large word like tulips when presented with a sequence of combinable short words like two lips. In Experiment 2 priming is found for the meaning of the second short word in similar sequences (e.g., lips in two lips). Finally, Experiment 3 demonstrates that listeners do not show priming for a short word like lips when it is pronounced as part of a larger word like tulips. The results of these experiments show that listeners sometimes access words other than those intended by speakers, and that they may simultaneously access words associated with several alternative parses of ambiguous sequences. Furthermore, they suggest that acoustic marking of word onsets places constraints on the success of lexical access. To account for these results, we present a new model of lexical access and segmentation, the Good Start model, which gives a principled account of these properties. DTIC

PROCEEDINGS OF THE GOVERNMENT USERS WORKSHOP ON GROUND PENETRATING RADAR APPLICATIONS AND EQUIPMENT Final Report
Dwain K. Butler Dec. 1992 97 p Workshop held in Vicksburg, MS, 26-27 Mar. 1992
(AD-A261873; WES/MP/GL-92-40) Avail: CASI HC A05/MF A02

The first Government Users Workshop on Ground Penetration Radar (GPR) Applications and Equipment attracted 60 attendees from 17 government agencies/offices and private industry. Presentations emphasized the wide variety of applications of GPR and current and emerging technology in GPR equipment. The workshop included field demonstrations at the Waterways Experiment Station Environmental Geophysics Training Facility. A concluding panel discussion summarized the highlights of the workshop and discussed research and development needs and requirements. DTIC

PROPERTIES OF READINGS OF PERIODICALLY CORRELATED RANDOM PROCESSES
Ya P. Dragan 27 Jan. 1993 9 p Transl. into ENGLISH from Orbor i Peredacha Informatsii (USSR), no. 33, 1972 p 7-12
(AD-A261225; FASTC-ID(RS)T-0561-92) Avail: CASI HC A02/MF A01

Periodically correlated random processes, which serve as models for natural rhythmic phenomena, are a generalization of amplitude modulation. It is noted in work that the operation of modulation is not invariant, since the phase of the carrier introduces a specific time structure, but it is invariant in the case of carriers which are multiples of the period of the carriers. Therefore there is interest in the investigation of the properties of readings of a periodically correlated random process (PKSP) in points which are multiples of the period of the correlated state. GEOLOCATION OF AN ELECTROMAGNETIC EMITTER USING A CYCLOSTATIONARY TIME DIFFERENCE OF ARRIVAL TECHNIQUE M.S. Thesis
Timothy A. Benson 17 Dec. 1992 88 p
(AD-A261781) Avail: CASI HC A05/MF A01

Many applications of signal processing require that the location of an electromagnetic emitter be determined. An algorithm is used to geolocate such an emitter. Special features of the algorithm not only allow the detection of cyclostationary signals in strong negative signal to noise ratio environments, but also discriminate against unwanted signals not of interest that may either occupy the same frequency band or have similar signal characteristics as the signal of interest. This is accomplished by determining spectral correlation densities for cycle frequencies equal to various exploitable features of the binary phase shift keying (bpsk) direct sequence spread spectrum signal. A COMPARISON OF IONOSPHERIC PROPAGATION MODE DELAY PREDICTIONS FROM ADVANCED PROPHET 4.3 WITH MEASURED DATA M.S. Thesis
Jose L. Nadal 15 Dec. 1992 63 p
(AD-A261782) Avail: CASI HC A04/MF A01

The outputs of the ionospheric propagation prediction model ADVANCED PROPHET 4.3 are compared to measurements of propagation mode delay for a high frequency communications link between Monterey and San Diego, California. Mode delay variations throughout the day are presented for experimental data and PROPHET predictions. A margin of error of less than 0.5 msec was considered acceptable and the number of acceptable predictions per day was generated. Acceptable predicted data collected over the test period was analyzed to establish which hours of the day PROPHET accurately predicts propagation mode delay, independent of frequency, date, and power levels. During the first six hours of the day PROPHET data tracks experimental data for mode delay change patterns. On a daily basis, predictions are best between 1400 and 1700 GMT (0600 and 0900 local time), although patterns could not be established for other hours of the day. Predicted mode delay percentage distributions show greater correlation during the first three hours of the morning and at sunset. DTIC

(NASA-TM-106096; E-7737; NAS 1.15:106096) Avail: CASI HC A03/MF A01

The effects of nuclear radiation and high temperature environments must be fully known and understood for the electronic components and materials used in both the Power Conditioning and Control subsystem and the reactor Instrumentation and Control subsystem of future high capacity nuclear space power systems. This knowledge is required by the designer of these subsystems in order to develop highly reliable, long-life power systems for future NASA missions. A review and summary of the experimental results obtained for the electronic components and materials investigated under the power management element of the Civilian Space Technology Initiative (CSTI) high capacity power project are presented: (1) neutron, gamma ray, and temperature effects on power semiconductor switches, (2) temperature and frequency effects on soft magnetic materials; and (3) temperature effects on rare earth permanent magnets. R AND D OF TRANSMISSION LINES FOR ECH SYSTEM
K. Ohkubo, M. Hosokawa, S. Kubo, M. Sato, Y. Takita, and T. Kuroda Feb. 1993 21 p Submitted for publication
(NIFS-210) Avail: CASI HC A03/MF A01

The performance of oversized transmission elements for millimeter waves is measured and compared with the calculation which is based on the superposition of plane wave (SPW) and on Fresnel approximation in the Huygens-Kirchhoff integral. Mode conversion in the split waveguide is discussed from the viewpoint of on- and off-axes, and 90-degree elbow bend on phase correction is examined by using the SPW method. The design and experiment on the whispering gallery mode generator are described. A preliminary analysis of the rectangular wave guide with two corrugated plates and two plane walls is also carried out to obtain the Gaussian beam with a waist size of x-axis different from that of y-axis.

CHARACTERIZATION OF ELECTROCHEMICAL SYSTEMS AND BATTERIES: MATERIALS AND SYSTEMS
James McBreen 1992 12 p Presented at the DOE Battery Workshop, Argonne, IL, 16-17 Jun. 1992
(Contracts DE-AC02-76CH-00016; DE-FG05-89ER-45384)
(DE93-003472; BNL-48039; CONF-9206311-1) Avail: CASI HC A03/MF A01

Materials are a pacing problem in battery development. The battery environment, particularly in rechargeable batteries, places great demands on materials. Characterization of battery materials is difficult because of their complex nature. In many cases meaningful characterization requires in situ methods. Fortunately, several new electrochemical and spectroscopic techniques for in situ characterization studies have recently become available, and reports of new techniques have become more frequent. The opportunity now exists to utilize advanced instrumentation to define detailed features, participating chemical species, and interfacial structure of battery materials with a precision heretofore not possible. This overview gives key references to these techniques and discusses the application of x-ray absorption spectroscopy to the study of battery materials. DOE

LIQUID FILLED VARIABLE CAPACITOR Patent
Ronald J. Gripshover, inventor (to Navy) and David B. Fenneman, inventor (to Navy) 10 Nov. 1992 5 p Filed 30 Mar. 1982
(AD-D015639; US-Patent-5,162,972; US-Patent-Appl-SN-363691) Avail: US Patent and Trademark Office

A liquid filled variable capacitor or PFL which provides variable frequency, impedance, and pulse length without changing the capacitor or PFL hardware is described. The capacitor is constructed from two or more conducting surfaces. A dielectric fluid mixture separates the conductors. A fluid supply system furnishes the dielectric fluid mixture to the conductors and provides for varying of the dielectric constant of the fluid and thus the capacitor operating characteristics, by varying the mixture composition. The fluid supply system has a mixing tank connected to both a supply of high dielectric constant fluid and a supply of low dielectric constant fluid. The high dielectric constant fluid and low dielectric constant fluid are mixed proportionally to obtain a dielectric fluid having the desired dielectric constant. A pump conveys the dielectric fluid between the mixing tank and the conductors while a heat exchanger controls the temperature of the dielectric fluid. DTIC

NEW GROUND STATES IN UNCONVENTIONAL SUPERCONDUCTORS Ph.D. Thesis
Mario Palumbo 1992 129 p
Avail: Univ. Microfilms Order No. DA9301358

The properties of unconventional superconductors have recently been the subject of much theoretical inquiry, since both the high-T(sub c) and heavy fermion superconductors may have unconventional order parameters. The term unconventional refers to order parameters having a lower degree of symmetry than the normal state lattice. Such systems may therefore break rotational, time reversal, and translational symmetry, leading to a variety of novel effects. This thesis is devoted to the detailed analysis of one such effect. In particular, we show how an unconventional superconductor, in zero applied field, can be subject to a 'magnetic' instability, yielding a new ground state which breaks both translational and time reversal symmetry. From our analytic calculations we will make predictions about the form of the new ground state and the qualitative features of the H - T phase diagram. We continue our consideration of this system by performing global minimizations of the Ginzburg-Landau functional via the method of simulated annealing. This technique allows us to study the detailed form of the order parameter and magnetic field both with and without an applied field. We will present the results of these minimizations, and discuss to what degree they support out analytic work. Finally, we will present the results of microscopic calculations of the Ginzburg-Landau parameters using the weak coupling quasi-classical theory, including the effects of impurity scattering. The results of these calculations will be discussed in conjunction with the physical feasibility of our instability conditions. Dissert. Abstr.

Among the new facilities to be offered by the National Science Foundation through the National High Magnetic Field Laboratory (NHMFL) are pulsed fields that can only be achieved at a national user facility by virtue of their strength, duration, and volume. In particular, a 44 mm bore pulsed magnet giving a 60 tesla field for 100 ms is in the final design stage. This magnet will be powered by a 1.4 GW motor-generator at Los Alamos and is an important step toward proving design principles that will be needed for the higher field quasi-stationary pulsed magnets that this power source is capable of driving. THE SUB 60 ps TIMING RESOLUTION USING LARGE AREA SILICON AVALANCHE DIODES
A. Hauger, A. Hirsch, N. Porile, R. Scharenberg, B. C. Stringfellow, M. Tincknell (Purdue Univ., West Lafayette, IN.), and G. Rai Oct. 1992 4 p Presented at the IEEE Nuclear Science Symposium, Orlando, Fl, 26-31 Oct. 1992
(Contract DE-AC03-76SF-00098)
(DE93-007723; LBL-32289; CONF-921005-25) Avail: CASI HC A01/MF A01

The new generation of planned experiments in high energy and nuclear physics requires high pixel density time-of-flight detection systems which mark the occurrence of an event with sub-100 ps accuracy. Conventional fast phototubes and scintillators do not easily lend themselves to large scale mechanical and electrical integration and generally prove to be very expensive. As an alternative technology, we report on the development and optimization of Silicon Avalanche Diodes (AVD's). The project is in part strongly motivated by the STAR experiment planned for the Relativistic Heavy Ion Collider (RHIC) facility at BNL. The time-of-flight component of STAR is expected to operate in a 0.5T magnetic field and is highly segmented. DOE

RADIATION-HARDENED CONTROL SYSTEM
R. I. Vandermolen, S. F. Smith, and M. S. Emery 1993 6 p Presented at the 5th Topical Meeting on Robotics and Remote Systems, Knoxville, TN, 26-29 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-007248; CONF-930403-16) Avail: CASI HC A02/MF A01

A radiation-hardened bit-slice control system with associated input/output circuits was developed to prove that programmable circuits could be constructed to successfully implement intelligent functions in a highly radioactive environment. The goal for this effort was to design and test a programmable control system that could withstand a minimum total dose of 10(exp 7) rads gamma. The Radiation Hardened Control System (RHCS) was tested in operation at a dose rate that ranged up to 135 krad/h, with an average total dose of 10.75 Mrads. Further testing beyond the required 10(exp 7) rads was also conducted. RHCS performed properly through the target dose of 10(exp 7) rads, and sporadic intermittent failures in some programmable logic devices were noted after approximately 13 Mrads. DOE

ULTRAFAST MEASUREMENTS OF 200 GIGAHERTZ SCHOTTKY PHOTODIODES Ph.D. Thesis
Kathryn LiDessau 1992 139 p
Avail: Univ. Microfilms Order No. DA9302241

Photodetectors play a fundamental role in optical communication and measurement systems. In communications systems, faster detectors could enhance system bandwidths, increasing information transmission capacity. In measurement systems, high-speed photodetectors could measure picosecond optical waveforms from mode-locked lasers, and optical and optoelectronic devices. To date, the fastest reported Schottky photodiodes achieve bandwidths around 100 GHz. Because presently available oscilloscopes have bandwidths up to only 50 GHz, electro-optic sampling had to be used to measure the response of these photodetectors. The speed of the actual devices was indirectly determined by a deconvolution of the system response from the measured data. To overcome this measurement limitation, we have devised two new circuits which allow high-speed photodiodes to be used to measure laser pulses without using expensive sampling oscilloscopes or complex laser systems. The first is a high-speed Schottky photodiode monolithically integrated with an electronic sampler. With this circuit we were able to measure an impulse response with a 1.8 ps full-width at half-maximum, corresponding to a 3-dB bandwidth of 200 GHz. No deconvolution was required. The second circuit is a high-speed photodiode monolithically integrated with a microwave detector. By using this circuit to replace the nonlinear crystal in autocorrelation and cross-correlation setups, we were able to measure laser pulse durations with a temporal resolution of 1.4 ps. The main advantages that this second photodiode optoelectronic circuit has over the nonlinear crystal are that it is not wavelength specific and that it is sensitive to very low input optical powers. In addition in this thesis, electro-optic sampling measurements of a greater than 220 GHz GaAs Schottky photodiode are presented. Dissert. Abstr.

BBU CODE DEVELOPMENT FOR HIGH-POWER MICROWAVE GENERATORS
T. L. Houck, G. A. Westenskow, and S. S. Yu (California Univ., Berkeley. Lawrence Berkeley Lab.) Aug. 1992 5 p Presented at the 16th International LINAC Conference, Ottawa, Ontario, 23-28 Aug. 1992
(Contract W-7405-eng-48)
(DE93-007111; UCRL-JC-110197; CONF-9208109-75) Avail: CASI HC A01/MF A01

We are developing a two-dimensional, time-dependent computer code for the simulation of transverse instabilities in support of relativistic klystron-two beam accelerator research at LLNL. The code addresses transient effects as well as both cumulative and regenerative beam breakup modes. Although designed specifically for the transport of high current (kA) beams through traveling-wave structures, it is applicable to devices consisting of multiple combinations of standing-wave, traveling-wave, and induction accelerator structures. In this paper we compare code simulations to analytical solutions for the case where there is no RF coupling between

cavities, to theoretical scaling parameters for coupled cavity structures, and to experimental data involving beam breakup in the two traveling-wave output structure of our microwave generator. DOE

(DE93-007600; SAND-92-2103C; CONF-930394-2) Avail: CASI HC A01/MF A01

Failures (shorts) were observed in MIL-C-20 like, molded-case, radial-leaded, ceramic capacitors after a low-voltage, 85 percent -relative-humidity, 85 C test was performed. Case removal revealed silver whisker growth on the chips between the non-coated solder area of the end-terminations where the radial leads extend from the chip. Insulation-resistance failures were observed in MIL-C-123 like, molded-case, radial-leaded, ceramic capacitors after moisture resistance, normal voltage testing (MIL STD 202 Method 106) was performed. In the case of the MIL-C-123 capacitors, no silver migration was observed. Three lots of molded-case, radial-leaded, MIL-C-123 capacitors with experimental end-terminations, were fabricated by KEMET Electronics Corporation, Greenville, South Carolina from a single chip lot. Three control lots with standard silver end-terminations were also fabricated. Each of the control lots was processed with each of the experimental lots through the subsequent processing and testing steps. This paper describes the different end-terminations and testing and evaluation of these three experimental lots and their counterpart control lots. These included a 4,000-hour, 85 percent-relative humidity, 85 C test and multiple cycles of moisture, normal voltage (MIL STD 202 Method 106) tests. DOE

CHARACTERIZATION OF CERAMIC CAPACITORS FOR HIGH-VOLTAGE PULSE-DISCHARGE APPLICATIONS
C. A. Hall and E. L. Jacobs 1992 8 p Presented at the 13th Capacitor and Resistor Technology Symposium: CARTS 1993, Costa Mesa, CA, 8-11 Mar. 1993
(Contract DE-AC04-76DP-00789)
(DE93-007601; SAND-92-2120C; CONF-930394-3) Avail: CASI HC A02/MF A01

Energy-storage, high-current, pulse discharge capacitors have been of interest for some time in applications such as weapon firing sets, trigger circuits, and laser power sources. For high reliability and temperature stability reasons, these capacitors have typically utilized Mylar or mica-paper dielectrics for high-voltage applications in the 2 to 6-kV range with peak currents greater than 5 kA and rise times less than 100 ns. Because of their volumetric efficiency some multilayer ceramic (MLC) capacitors have been used for trigger applications to approximately 750 volts with 2 kA peak current and pulse widths of approximately 1.5 microns. More recently, MLC capacitors have been developed for output filters of switchmode, high-voltage power supplies. Dielectric materials and capacitor designs from several manufacturers have been characterized to explore higher voltage applications of MLC capacitors. This characterization includes high-current, pulse discharge mode testing at voltages up to 3.5 kV. This allows their applicability and reliability for the above applications to be assessed. Results of pulse discharge testing, employing a low inductance circuit, with typically 4 kA peak current and 200 ns pulse width, are reported. The usefulness and reliability of larger MLC capacitor values were explored for pulse widths up to 50 microns at typical peak currents of 700 A. Standard capacitor parameters for the various dielectrics also reported. Discharge life testing at varying temperatures and D.C. breakdown testing is used to provide initial estimates of reliability. Finally, MLC capacitor results are compared with a new relatively efficient dual dielectric (film/paper) design. DOE

DETECTING DAMAGED CABLES USING A PREIONIZED GAS TECHNIQUE
R. A. Vigil (Science and Engineering Associates, Inc., Albuquerque, NM.), M. J. Jacobus, and C. F. Nelson 1992 8 p The EPRI Workshop on Power Plant Cable Condition Monitoring held in San Francisco, CA, 9-11 Feb. 1993
(Contract DE-AC04-76DP-00789)
(DE93-007588; SAND-92-2917C; CONF-930254-2) Avail: CASI HC A02/MF A01

Because of the difficulty in conducting electrical tests on unshielded cables installed in conduits, experiments were conducted to develop a preionized gas condition monitoring technique to detect localized degradation of installed, unshielded cables in conduits. Breakdown testing of various types of damaged and undamaged cables was performed. Other test parameters examined were gas type, position of tie cable with respect to the conduit wall, length of cables, conduit configuration, conduit size, gas propagation in conduits, and other parameters necessary for practical implementation of the technique. The principal conclusion of the test program is that high potential testing of cables in the presence of preionized helium gas provides essentially the same information as high potential testing in water. Using helium requires no greater effort and eliminates the practical disadvantage of using water. A test criterion of 30 kVDC or 10 kVAC would detect when 5 mils of insulation remain on one particular tested cable. No undamaged cable was noted to break down at these voltages. A high concentration of helium is required to achieve these results, but this is easily attained. AC testing appears preferable to DC testing because of the variability testing. However, DC testing may warrant further investigation because of its inherent advantages. The level of damage that a cable can incur without compromising its functionality in an accident environment has not yet been determined and is a subject of ongoing research. DOE

Avalanche Photodiodes (APDs) operating in 'Geiger Mode' have been studied in a fibre tracking readout environment. A fast recharge circuit has been developed for high rate data taking, and results obtained from a model fibre tracker in the test beam at Brookhaven National Laboratory are presented. A high rate calibrated light source has been developed using a commercially available laser diode and has been used to measure the efficiency of the devices. The transmission of the light from a 1mm fibre onto a 0.5mm diameter APD surface has been identified as the main problem in the use of these particular devices for scintillating fibre tracking in the Superconducting Supercollider environment. Solutions to this problem are proposed. DOE

WALSH FUNCTION GENERATOR FOR THE ELECTRONICALLY SCANNED THINNED ARRAY RADIOMETER (ESTAR) INSTRUMENT
William A. Chren, Jr. Washington Apr. 1993 17 p
(RTOP 740-00-00)
(NASA-TM-4449; NAS 1.15:4449; Rept-93B00030) Avail: CASI HC A03/MF A01

A prototype Walsh Function Generator (WFG) for the ESTAR (Electronically Scanned Thinned Array Radiometer) instrument has been designed and tested. Implemented in a single Xilinx XC3020PC68-50 Field Programmable Gate Array (FPGA), it generates a user-programmable set of 32 consecutive Walsh Functions for noise cancellation in the analog circuitry of the Front-End Modules (FEM's). It is implemented in a 68-pin plastic leaded chip carrier (PLCC) package, is fully testable, and can be used for noise cancellation periods as small as 2 msec. Author

TUNED CIRCUIT ELECTRIC LEVITATION BEARINGS FOR MICROACTUATORS Ph.D. Thesis
Suresh Kumar 1992 197 p
Avail: Univ. Microfilms Order No. DA9235260

Micromachined sensors, actuators, and systems have recently come into their own as an exciting field with the promise of revolutionary applications in many diverse areas. At present, the ability of the micromotors

to reach their full potential is hindered by the presence of large friction forces that play a dominant role in the dynamic behavior. A novel design for substantially reducing or eliminating this friction by using tuned circuit electric levitation (TCEL) is examined in this thesis. This design utilizes a resonant circuit driven by a radio frequency AC voltage source for achieving stable levitation. The main advantages of TCEL are stable levitation without requiring a feedback sensor and the ability to produce torque and motion using identical components of an existing micromotor design. This thesis analyzes the dynamics of electrically levitated systems, and derives stability conditions for such systems. TCEL is shown to be statically stable if the frequency of the source is greater than the natural frequency of the resonant circuit at equilibrium. The analysis shows that some electrically levitated systems can exhibit dynamic instability, but most of the practical designs are stable. The analysis also reveals that four independent tuned circuits can be used to stabilize a freely levitated object in all six degrees of freedom. An experimental demonstration of the stability of a TCEL system is also presented in this thesis. A small flat plate is levitated using four tuned circuits, and its stability is confirmed by photographing the gap between the suspended plate and the stator seen through a microscope. In addition, measurements of the plate position and orientation are presented, which are in good agreement with the theory. An experimental actuator utilizing the electric levitation is also presented. The tuned circuits are used to provide vertical stability as well as part of the motive force in the experiment, demonstrating the use of TCEL as a microbearing.

During the past quarter we have fabricated and tested a 12-bit by 16-bit multiplier based on our previous multiplier architecture but using third order recoding. That is, we use an 8-to-1 multiplexer selected by 3 input bits to form each partial product instead of the 4-to-1 multiplexer selected by 2 input bits as used previously. The partial products (1X, 3X, 5X, and 7X the coefficient value) are stored in an on-chip RAM. DTIC

THE 0.3 mm DIAMETER FLEXIBLE AMPEROMETRIC LACTATE PROBE Technical Report, Oct. 1992 - Nov. 1993
Dan L. Wang and Adam Heller 26 Jan. 1993 31 p
(AD-A260826; TR-003) Avail: CASI HC A03/MF A01

A flexible lactate electrode was made of 400 +/- 100 7 micrometers diameter carbon fibers, epoxy embedded in a 0.3 mm diameter polyimide tubing. The electrode was modified by precipitating on it the relatively insoluble complex formed between 1100 kd partially N-ethylamine quaternized poly((vinylpyridine)Os(bipyridine)2Cl)Cl (POs-EA) and lactate oxidase. The steady-state lactate electrooxidation current, at 2mM lactate concentration and at 22 C, was 4OO nA. The 5O +/- 10 microA/sq cm current density and the 2OmA/sq cm/M sensitivity decreased only by 5 percent upon increasing the partial pressure of oxygen from 0.0 to 0.2 atm. The electrode retains its sensitivity after dry storage at 4 C for 4 months in air but loses at 37 C half of its sensitivity in 7 hours through polymer desorption when operated at 0.4V (SCE). DTIC

(Contract N00019-89-C-0152)
(AD-A261178; FR-10119) Avail: CASI HC A04/MF A01

Under the MIMIC Program, Spire has pursued improvements in the manufacturing of low cost, high quality gallium arsenide MOCVD wafers for advanced MIMIC FET applications. As a demonstration of such improvements, Spire was tasked to supply MOCVD wafers for comparison to MBE wafers in the fabrication of millimeter and microwave integrated circuits. In this, the final technical report for Spire's two-year MIMIC contract, we report the results of our work. The main objectives of Spire's MIMIC Phase 3 Program, as outlined in the Statement of Work, were as follows: Optimize the MOCVD growth conditions for the best possible electrical and morphological gallium arsenide. Optimization should include substrate and source qualification as well as determination of the optimum reactor growth conditions; Perform all work on 75 millimeter diameter wafers, using a reactor capable of at least three wafers per run; and Evaluate epitaxial layers using electrical, optical, and morphological tests to obtain thickness, carrier concentration, and mobility data across wafers. A DESIGN OF A FAST AND AREA EFFICIENT MULTI-INPUT MULLER C-ELEMENT Research Report
Tzyh-Yung Wuu and Sarma B. Vrudhula Jan. 1993 15 p
(Contract MDA903-92-D-0020)
(AD-A261002; ISI/RR-93-302) Avail: CASI HC A03/MF A01

A multi-input Muller C-element has frequently been used for joining signal transitions or completion time detection in self-timed circuits. This paper presents an n-input Muller C-element design which uses the multi-level login design technique and has a symmetric format for any integer n greater than 2. In comparison with series-parallel MOS structure implementations and C-element tree implementations, our design has fewer restrictions in terms of n, less path delay, less delay variance from inputs to output, and less area consumption. Experimental validation in this paper is based on an industrial standard cell library. DTIC

(Contract N00014-90-C-0226; ARPA Order 7534)
(AD-A260589) Avail: CASI HC A07/MF A02

The objective of the contract was to conduct research to integrate semiconductor electronics with infrared sensors, based upon high transition temperature superconducting microbolometers, to make a 16 pixel (4x4) two-dimensional infrared staring array. This technology should enable us to eventually fabricate large area, high performance IR arrays using conventional silicon IC processing technology for cost-effective systems. Deliverables included quarterly reports, this final report, and a 16 pixel (4x4) two-dimensional superconducting microbolometer array including transistor switches at the pixels and drive electronics mounted in a Dewar. All items were delivered. DTIC

UTILIZATION OF AN ELECTRONIC CIRCUIT SIMULATOR IN CMOS LATCH-UP STUDIES
L. Varga Jun. 1992 42 p
(AD-A260877; DREO-1144) Avail: CASI HC A03/MF A01

The 2-D device simulator presented in this work allows the investigation of the effect of ionizing radiation dose rate on the performance of CMOS circuits. The simulator is composed of two parts, a diffusion current module and a lumped-element module. The first module solves the current transport equations with the aid of the HSPICE code. The lumped-element module then simulates the electrical characteristics of the parasitic pnpn structure (present in CMOS circuits) using the results from the first module as input

parameters. The model was applied to study the latch-up vulnerability of a CMOS inverter as a function of circuit layout and distribution of substrate contacts. Results of radiation hardening efforts are presented. DTIC

Int-Patent-Class-G01R-27/26) Avail: US Patent and Trademark Office

A phase discriminating capacitive sensor array system which provides multiple sensor elements which are maintained at a phase and amplitude based on a frequency reference provided by a single frequency stabilized oscillator. Sensor signals provided by the multiple sensor elements are controlled by multiple phase control units, which correspond to the multiple sensor elements, to adjust the sensor signals from the multiple sensor elements based on the frequency reference. The adjustment made to the sensor signals is indicated by output signals which indicate the proximity of the object. The output signals may also indicate the closing speed of the object based on the rate of change of the adjustment made, and the edges of the object based on a sudden decrease in the adjustment made. CROSS-SWITCHED MICRAD SEEKER Patent
Frederick C. Alpers, inventor (to Navy) and Mervyn C. Hoover, inventor (to Navy) 3 Nov. 1992 13 p Filed 27 Aug. 1984
(AD-D015676; US-Patent-5,160,934; US-Patent-Appl-SN-649501;
US-Patent-Class-342-351) Avail: US Patent and Trademark Office

A MICrowave RADiometric (MICRAD) guidance system is disclosed which utilizes an antenna having four beams. The beams are designated right, left, up, and down. Information from the four beams is monitored essentially 100 percent of the time by passing through appropriate ferrite cross-switching means to four separate receivers. Information from two of the receivers passes through a first multiplexer and feedback gain balancer to provide a target azimuth output, and information from the remaining two receivers passes through a second multiplexer and feedback gain balancer to provide a target elevation output. A local oscillator heterodynes each of the four receivers in common, and a switch driver couples each of the multiplexers to the ferrite cross-switching means and gain balancers for appropriate selection. Recently there has been a strong interest in producing negatively charged ion beams such as H-, for space based accelerators. The negative ions are generated in the plasma of an arc or glow discharge. The electrons are separated from the negative ions by a magnetic field. In such an environment, various plasma and discharge instabilities can occur resulting in an undesirable Megahertz noise of broad spectrum in the beam. It has been experimentally shown that the noise could be reduced by using a large ballast resistor in the discharge circuit. However to effectively suppress the noise, the value of the resistance would be prohibitively high. This report describes the design of a possible noise suppression circuit utilizing power transistors in a pulsed discharge. Using power transistors it is possible to obtain high dynamic impedance, but with sufficiently low D.C. resistance to stabilize the instabilities. The noise is present within a Negative Ion Source obtained from Los Alamos National Laboratory (AT division). This report describes the design of a Gate Turnoff Thyristor (GTO) pulsing circuit for the Negative Ion Source which includes the modification of an existing gate drive unit for a low power GTO. The Negative Ion Source had been pulsed by a capacitive bank discharge circuit. This GTO pulsing circuit has been successfully tested on a Hollow Cathode discharge. DTIC

VARIABLE PULSE RATE CIRCUIT Patent
Edwin E. Westerfield, inventor (to Navy), Larry L. Warnke, inventor (to Navy), and William S. Devereux, inventor (to Navy) 20 Oct. 1992 7 p Filed 28 Jan. 1988
(AD-D015675; US-Patent-5,157,695; US-Patent-Appl-SN-149298;
US-Patent-Class-375-96) Avail: US Patent and Trademark Office

A variable pulse rate circuit for correlating a locally generated code with a code that is being transmitted by a space vehicle is described. A computer means is used for providing a binary word to a latch. The binary word in the latch is used in turn by a delay line, to control the amount of delay that is presented to pulses. The pulses are emitted by a pulse generator having a fixed rate reference. The pulse rate, of pulses being emitted by of the delay line, is varied from the reference pulse rate. This variation is the result of computer means that rapidly changes the amount of delay of the delay line. The pulse rate and the pulse phase are varied in order to cause a locally generated code to become phase aligned with the code received from the space vehicle. The space vehicle is tracked using the variable pulse rate circuit. DTIC

INVESTIGATION OF A BACKGROUND SUPPRESSION TRANSIMPEDANCE AMPLIFIER FOR PHOTOVOLTAIC DETECTORS M.S. Thesis
Ferdinand J. Metzger, Jr. Dec. 1992 69 p
(AD-A261828) Avail: CASI HC A04/MF A01

The current generation of transimpedance amplifier based detector systems are limited by opamp saturation when operating at a high gain or in the presence of a large background signal. To eliminate saturation, an amplifier that is frequency dependent is developed. Additionally, the noise sources in the conventional transimpedance amplifier and photovoltaic detector are quantified for comparison to any modified circuit. Initial results indicate that the frequency dependent detector system is a viable system, however, further development is required. Further research of this technology is expected to support future infrared and long range detection applications. DTIC

Certain gyro-type electron beam devices require two tandem coaxial chambers with different uniform axial magnetic fields in their interiors. Therefore, there is a step in the field profile in the vicinity of the junction of the two chambers, which are sometimes of different diameter as well. An electric solenoid is usually employed to furnish such a field but the sources are bulky, cumbersome, and consumptive of energy, and provide only rough approximations to the ideal field profile. This report describes a permanent magnet field source that was designed to provide a constant axial field of 2 kOe in the larger of the two chambers and 0.5 kOe in the smaller. The basic field is provided by two tandem permanent magnet solenoids. The rather broad transition between the field values in the two chambers is considerably narrowed (approximately 50 percent) by the placement of a radially magnetized ring internal to the junction of the two solenoids. The field profile can be made to conform to that specified to within a few percent by addition of two axially magnetized rings. DTIC

RF VACUUM MICROELECTRONICS Quarterly Technical Report No. 3, 1 Oct. - 31 Dec. 1992
31 Dec. 1992 14 p
(Contract MDA972-92-C-0034; ARPA Order 8162)
(AD-A261343) Avail: CASI HC A03/MF A01

Findings from the first mask set that influenced the design of the second mask set were as follows: (1) The original size of a chip was

based on experience with semiconductor devices and was too small to dice adequately on the silver substrates; (2) The one micron emitter tips were too small and had fully open gate apertures on only a few samples. As a result, the relative number of one micron pyramids should be much less than 1.5, 2.0 and 2.5 micrometer pyramids. The three larger sizes were, in general, properly formed on all samples; (3) As a result of the large number of arrays on each chip, only a small fraction could be bonded to the header. Furthermore, the bonding pad arrangement made it difficult to run bond wires in certain directions without the wires crossing over an emitter array; (4) Scribe streets were located too near the bond pads and may have resulted in some emitter to gate short circuits; and (5) Dimensional stability of the silver substrates caused some misalignment of the gate metal to the emitter tips resulting in emitters on the edge of an array not being properly formed. DYNAMIC BEHAVIOR OF HELIX INTERACTION CIRCUITS In-House Report, Oct. 1990 - May 1992
Peter J. Rocci Dec. 1992 39 p
(AD-A261362; RL-TR-92-298) Avail: CASI HC A03/MF A01

The dynamic behavior of a high power traveling wave tube's (TWT) helix interaction circuit was determined while operating in its system environment. The purpose of this effort was to develop a fundamental knowledge base of material interactions under thermal loading, develop an understanding of long-term thermal effects on materials and to develop a relationship to TWT performance and reliability. The interaction circuit for the TWT analyzed consists of a variable pitch tungsten helix, three beryllia support rods spaced at equal 120 degree intervals around the helix, and a stainless steel barrel which encloses the vacuum envelope. A three-dimensional finite element model was constructed that represented the entire interaction circuit (89 helix turns in length). There was a great deal of complexity associated with the development of this model due to the irregular 'T-shaped' cross-section of the support rods and variation in pitch of the helix. Upon completion, the model contained approximately 18,000 elements and 45,000 nodes. DTIC

The objective of this DARPA research project was to develop real-time control systems using in-situ sensors for semiconductor manufacturing. Our initial application was the development of a temperature control system for Rapid Thermal Processing (RTP) equipment. We developed mathematical models of RTP, analyzed them. identified and validated these models, deduced several control algorithms, and finally applied them to real systems at Stanford University and at Texas Instruments. Also, based on our analysis, we modified the design of the system hardware (lamp array) and also proposed an optimal lamp array design technique. DTIC

The 1992 annual report of research conducted in the Electronics Research Laboratory at University of California at Berkeley under the sponsorship of the Joint Services Electronics Program is presented. The research covers the following project areas: (1) quantum electronic devices: nonlinear optics in compound semiconductors, ultrafast optical techniques, and optical probing of semiconductor devices and interfaces by electro-optic and photo-elastic effects; (2) electronic devices: 0.1 micron BiCMOS devices in sulk and SOI substrates, conductive oxides and ferroelectrics for programmable devices, and insulated-gate GaAs field effect transistors; and (3) neural networks and parallel computation: stochastic neural networks and application to signal processing, learning and generalization by neural networks, reconfigurable analog elements for neural nets, and architectural issues in parallel computation. There is also a section concerning significant accomplishments. Two supplemental reports are included. An appendix of all publications, papers, and presentations forms a second part. It is bound under separate cover. DTIC

(AD-A261784) Avail: CASI HC A03/MF A01

We summarize our fifth quarter results and discuss plans for the remainder of the baseline program which is to demonstrate a thin film edge emitter triode with 10 micro-A/micrometer emission current density at less than 250V and which can be modulated at 1 GHz for 1 hour. We completed fabrication of the first thin film edge emitter vacuum transistors this quarter. Extensive DC characterization has been carried out. Triode characteristics have been observed on many devices. Low frequency (1 KHz) modulation of the devices has been shown. Parametric testing shows these devices to have the high currents (50 micro-A), high current densities (10 micro-A/mM) and transconductances (1.5 micro-S necessary to achieve 1 GHz operation. High frequency testing is currently underway. DTIC

LARGE AREA, LOW CAPACITANCE Si(Li) DETECTORS FOR HIGH RATE X RAY APPLICATIONS
C. S. Rossington, P. M. Fine, and N. W. Madden Oct. 1992 7 p Presented at the Institute of Electrical and Electronic Engineers (IEEE) Nuclear Science Symposium, Orlando, FL, 26-31 Oct. 1992
(Contract DE-AC03-76SF-00098)
(DE93-007661; LBL-32243; CONF-921005-26) Avail: CASI HC A02/MF A01

Large area, single-element Si(Li) detectors have been fabricated using a novel geometry which yields detectors with reduced capacitance and hence reduced noise at short amplifier pulse-processing times. A typical device employing the new geometry with a thickness of 6 mm and an active area of 175 mm 2 has a capacitance of only 0.5 pf, compared to 2.9 pf for a conventional planar device with equivalent dimensions. These new low capacitance detectors, used in conjunction with low capacitance field effect transistors, will result in x-ray spectrometers capable of operating at very high count rates while still maintaining excellent energy resolution. The spectral response of the low capacitance detectors to a wide range of x-ray energies at 80 K is comparable to typical state-of-the-art conventional Si(Li) devices. In addition to their low capacitance, the new devices offer other advantages over conventional detectors. Detector fabrication procedures, I-V and C-V characteristics, noise performance, and spectral response to 2-60 keV x-rays are described. DOE

A THREE-DIMENSIONAL ALGEBRAIC GRID GENERATION SCHEME FOR GAS TURBINE COMBUSTORS WITH INCLINED SLOTS Final Report
S. L. Yang, M. C. Cline (Los Alamos National Lab., NM.), R. Chen, and Y. L. Chang Mar. 1993 25 p
(Grant NAG3-1109; RTOP 537-02-20)
(NASA-CR-191095; E-7674; NAS 1.26:191095) Avail: CASI HC A03/MF A01

A 3D algebraic grid generation scheme is presented for generating the grid points inside gas turbine combustors with inclined slots. The scheme is based on the 2D transfinite interpolation method. Since the scheme is a 2D approach, it is very efficient and can easily be extended to gas turbine combustors with either dilution hole or slot configurations. To demonstrate the feasibility and the usefulness of the technique, a numerical study of the quick-quench/lean-combustion (QQ/LC) zones of a staged turbine combustor is given. Preliminary results illustrate some of the major features of the flow and temperature fields in the QQ/LC zones. Formation of co- and counter-rotating bulk flow and shape temperature fields can be observed clearly, and the resulting patterns are consistent with experimental observations typical of the confined slanted jet-in-cross flow. Numerical solutions show the method to be an efficient and reliable tool for generating computational grids for analyzing gas turbine combustors with slanted slots. Author

COMPUTATION OF HYPERSONIC VISCOUS FLOWFIELDS USING THE PARABOLIZED NAVIER-STOKES EQUATIONS Ph.D. Thesis
Reinhold Alfred Gerbsch 1992 205 p
Avail: Univ. Microfilms Order No. DA9235897

A new, explicit, non-iterative, finite-volume algorithm based on Osher's upwind method is applied to the three-dimensional parabolized Navier-Stokes equations to model hypersonic flowfields. The algorithm includes real-gas effects and turbulence modeling and is second-order accurate. Flux limiters are added to make the scheme total variation diminishing. The streamwise pressure gradient is limited to the subsonic regions to maintain a hyperbolic inviscid equation set. Second-order central-differencing is applied to the viscous terms and upwind differencing is applied to the inviscid terms in both the subsonic and supersonic portions of the flowfield. The new algorithm is validated by computing laminar and turbulent-flow cases in both two and three dimensions. Results are compared with experimental data, analytical solutions and results from other numerical algorithms. Solutions obtained with the new algorithm agree well with other computational techniques and experimental data. The upwind technology results in robust algorithm which exhibits excellent shock capturing and the capability to resolve discontinuities. For the class of flows studied, the different upwind methods yield very similar results. Dissert. Abstr.

A CONVERGENT FINITE DIFFERENCE SCHEME FOR THE NAVIER-STOKES EQUATIONS OF NONISENTROPIC COMPRESSIBLE FLUID FLOW Ph.D. Thesis
Jing Zhao 1992 184 p
Avail: Univ. Microfilms Order No. DA9301485

The main result of this work is an analysis of a finite difference scheme for the Navier-Stokes equations which model nonisentropic, compressible fluid flow in one space dimension. Convergence is proved and error bounds are derived for the scheme. The error is measured in the L(exp 2) norm for u and e; and in the piecewise H(exp 1) norm for v. It is noteworthy that the error bounds dominate sup-norm error bounds for discontinuous variable v. It is shown that the scheme converges at a rate of O(delta x(sup r)) (r less than 1/12) if the initial data is discontinuous, and a O(delta x(sup 1/2)) if the initial data is continuous. Numerical results are also presented in the last part of the dissertation. Dissert. Abstr.

(DE93-000112; DOE/BC-14600/38; SUPRI-TR-89) Avail: CASI HC A03/MF A01

One of the most important tools in production logging and well testing is the downhole flowmeter. Unfortunately, existing tools are inaccurate outside of an idealized single phase flow regime. Spinner tools are inaccurate at extremely high or low flow rates and when the flow rate is variable. Radioactive tracer tools have similar inaccuracies and are extremely sensitive to the flow regime. Both tools completely fail in the presence of multiphase flow, whether for gas/oil, gas/water, or fluid/solid. Downhole flowmetering is important for locating producing zones and thief zones and monitoring production and injection rates. The effects of stimulation can also be determined. The goal of this project is the investigation of accurate downhole flowmetering techniques for all single phase flow regimes and multiphase flows. The measurement method investigated in this report is the use of ultrasound. There are two ways to use ultrasound for fluid velocity measurement. The first method, examined in Chapter 2, is the contrapropagation, or transit-time, method which compares travel times with and against fluid flow. Chapter 3 details the second method which measures the Doppler frequency shift of a reflected sound wave in the moving fluid. Both of these technologies need to be incorporated in order to build a true multiphase flowmeter. Chapter 4 describes the proposed downhole multiphase flowmeter. DOE

MINIMIZATION OF HEAT SLAB NODES WITH HIGHER ORDER BOUNDARY CONDITIONS
Charles W. Solbrig 1992 12 p Presented at the Joint American Nuclear Society (ANS)/European Nuclear Society (ENS) International Meeting on Fifty Years of Controlled Nuclear Chain Reaction: Past, Present, and Future, Chicago, IL, 15-20 Nov. 1992
(Contract W-31-109-eng-38)
(DE93-004238; ANL/CP-76463; CONF-921102-48) Avail: CASI HC A03/MF A01

The accuracy of a numerical solution can be limited by the numerical approximation to the boundary conditions rather than the accuracy of the equations which describe the interior. The study presented in this paper compares the results from two different numerical formulations of the convective boundary condition on the face of a heat transfer slab. The standard representation of the boundary condition in a test problem yielded an unacceptable error even when the heat transfer slab was partitioned into over 300 nodes. A higher order boundary condition representation was obtained by using a second order approximation for the first derivative at the boundary and combining it with the general equation used for inner nodes. This latter formulation produced reasonable results when as few as ten nodes were used. DOE

EXPERIMENTAL AND THEORETICAL STUDIES OF DENSE FLUID MIXTURES
Dec. 1992 5 p
(Contract DE-FG02-86ER-13623)
(DE93-006070; DOE/ER-13623/3) Avail: CASI HC A01/MF A01

During the thirty-one months of this grant, extensive measurements of the speed of sound in three alternative refrigerants and in SF6 were conducted. Modifications and improvements were made to the equipment for measuring interfacial tension in pure fluids and mixtures, and a new set of measurements of interfacial tension over a wide range of temperature and pressure conditions for three mixtures of simple fluids was conducted. The results of these interfacial tension measurements were used to show that the new corresponding states theory of the variation of surface tension with temperature and composition is superior to the previous corresponding states theory. Computer simulations were performed on a system of molecules interacting via a Lennard-Jones potential that contained two liquid-vapor interfaces. Careful attention to the parameters of the simulation and to achievement of equilibrium illuminated problems that had plagued earlier simulations. DOE

PROPAGATION VELOCITY AND SPACE-TIME CORRELATION OF PERTURBATIONS IN TURBULENT CHANNEL FLOW
John Kim and Fazle Hussain (Houston Univ., TX.) May 1992 49 p
(RTOP 505-60-00)
(NASA-TM-103932; A-92088; NAS 1.15:103932) Avail: CASI HC A03/MF A01

A database obtained from direct numerical simulation of a turbulent channel flow is analyzed to extract the propagation velocity V of velocity, vorticity, and pressure fluctuations from their space-time correlations. A surprising result is that V is approximately the same as the local mean velocity for most of the channel, except for the near-wall region. For y(+) is less than or equal to 15, V is virtually constant, implying that perturbations of all flow variables propagate like waves near the wall. In this region V is 55 percent of the centerline velocity U(sub c) for velocity and vorticity perturbations and 75 percent of U(sub c) for pressure perturbations. Scale-dependence of V is also examined by analyzing the bandpass filtered flow fields. Comprehensive documentation of the propagation velocities and space-time correlation data, which should prove useful in the evaluation of Taylor's hypothesis is presented. An attempt was made to explain some of the data in terms of our current understanding of organized structures, although not all of the data can be explained this way. Author (revised)

A FEASIBILITY STUDY OF USING LANGLEY 0.3-m TRANSONIC CRYOGENIC TUNNEL SIDEWALL BOUNDARY-LAYER REMOVAL SYSTEM FOR HEAVY GAS TESTING Final Report
A. V. Murthy, S. Balakrishna, and W. Allen Kilgore Mar. 1993 25 p
(Contract NAS1-18585; RTOP 505-59-86-02)
(NASA-CR-191438; NAS 1.26:191438) Avail: CASI HC A03/MF A01

This report presents the results of a preliminary study for using the 0.3-m Transonic Cryogenic Tunnel sidewall boundary-layer removal system with heavy gas sulfur hexafluoride as the test medium. It is shown that the drive motor speed/power of the existing system and the additional heat load on the tunnel heat exchanger are the major problems limiting the boundary-layer removal system performance. Overcoming these problems can provide the capability to remove about 1.5 percent of the test section mass flow at Mach number M = 0.8 and about 5 percent at M = 0.25.

Previous studies have shown that these boundary-layer mass flow removal rates can reduce the boundary-layer thickness by a factor of two at the model station. Also the effect of upstream boundary-layer removal on the airfoil test data is not likely to be significant under high lifting conditions. Near design conditions, corrections to the test Mach number may be necessary to account for sidewall boundary-layer effects. Author (revised)

PREDICTION OF UNSTEADY FLOWS IN TURBOMACHINERY USING THE LINEARIZED EULER EQUATIONS ON DEFORMING GRIDS Final Technical Report

William S. Clark and Kenneth C. Hall Apr. 1993 110 p

(Grant NAG3-1192)

(NASA-CR-192919; NAS 1.26:192919) Avail: CASI HC A06/MF A02

A linearized Euler solver for calculating unsteady flows in turbomachinery blade rows due to both incident gusts and blade motion is presented. The model accounts for blade loading, blade geometry, shock motion, and wake motion. Assuming that the unsteadiness in the flow is small relative to the nonlinear mean solution, the unsteady Euler equations can be linearized about the mean flow. This yields a set of linear variable coefficient equations that describe the small amplitude harmonic motion of the fluid. These linear equations are then discretized on a computational grid and solved using standard numerical techniques. For transonic flows, however, one must use a linear discretization which is a conservative linearization of the nonlinear discretized Euler equations to ensure that shock impulse loads are accurately captured. Other important features of this analysis include a continuously deforming grid which eliminates extrapolation errors and hence, increases accuracy, and a new numerically exact, nonreflecting far-field boundary condition treatment based on an eigenanalysis of the discretized equations. Computational results are presented which demonstrate the computational accuracy and efficiency of the method and demonstrate the effectiveness of the deforming grid, far-field nonreflecting boundary conditions, and shock capturing techniques. A comparison of the present unsteady flow predictions to other numerical, semi-analytical, and experimental methods shows excellent agreement. In addition, the linearized Euler method presented requires one to two orders-of-magnitude less computational time than traditional time-marching techniques making the present method a viable design tool for aeroelastic analyses.

IMPLEMENTATION OF THE TURN FUNCTION METHOD IN A THREE-DIMENSIONAL, PARALLELIZED HYDRODYNAMICS CODE

P. J. ORourke and M. S. Fairfield 1992 22 p Presented at the 1993 International Simulators Conference on High Performance Computing, Arlington, VA, 29 Mar. - 1 Apr. 1993

(Contract W-7405-eng-36)

(DE93-003744; LA-UR-92-3468; CONF-930372-1) Avail: CASI HC A03/MF A01

The implementation of the Turn Function Method in KIVA-F90, a version of the KIVA computer program written in the FORTRAN 90 programming language that is used on some massively parallel computers is described. The Turn Function Method solves both linear momentum and vorticity equations in numerical calculations of compressible fluid flow. Solving a vorticity equation allows vorticity to be both conserved and transported more accurately than in traditional methods for computing compressible flow. This first implementation of the Turn Function Method in a three-dimensional hydrodynamics code involved some modification of the original method and some numerical difference approximations. In particular, a penalty method is used to keep the divergence of the computed vorticity field close to zero. Difference operators are also defined in such a way that the finite difference analog of del(del x u) = 0 is exactly satisfied. Three example problems show the increased computational cost and the accuracy to be gained by using the Turn Function Method in calculations of flows with rotational motion. Use of the Method can increase by 60 percent the computational times of the Euler equation solver in KIVA-F90, but it is concluded that this increased cost is justified by the increased accuracy. NONLINEAR EVOLUTION OF THE FIRST MODE SUPERSONIC OBLIQUE WAVES IN COMPRESSIBLE BOUNDARY LAYERS. PART 1: HEATED/COOLED WALLS

J. S. B. Gajjar (Manchester Univ., England.) Mar. 1993 32 p

(Contract NCC3-233; RTOP 505-62-21)

(NASA-TM-106087; ICOMP-93-08; E-7718; NAS 1.15:106087) Avail: CASI HC A03/MF A01

The nonlinear stability of an oblique mode propagating in a two-dimensional compressible boundary layer is considered under the long wave-length approximation. The growth rate of the wave is assumed to be small so that the concept of unsteady nonlinear critical layers can be used. It is shown that the spatial/temporal evolution of the mode is governed by a pair of coupled unsteady nonlinear equations for the disturbance vorticity and density. Expressions for the linear growth rate show clearly the effects of wall heating and cooling and in particular how heating destabilizes the boundary layer for these long wavelength inviscid modes at O(1) Mach numbers. A generalized expression for the linear growth rate is obtained and is shown to compare very well for a range of frequencies and wave-angles at moderate Mach numbers with full numerical solutions of the linear stability problem. The numerical solution of the nonlinear unsteady critical layer problem using a novel method based on Fourier decomposition and Chebychev collocation is discussed and some results are presented. COMBINED LAURA-UPS HYPERSONIC SOLUTION PROCEDURE

William A. Wood and Richard A. Thompson Mar. 1993 24 p

(RTOP 506-40-91-01)

(NASA-TM-107682; NAS 1.15:107682) Avail: CASI HC A03/MF A01

A combined solution procedure for hypersonic flowfields around blunted slender bodies was implemented using a thin-layer Navier-Stokes code (LAURA) in the nose region and a parabolized Navier-Stokes code (UPS) on the after body region. Perfect gas, equilibrium air, and non-equilibrium air solutions to sharp cones and a sharp wedge were obtained using UPS alone as a preliminary step. Surface heating rates are presented for two slender bodies with blunted noses, having used LAURA to provide a starting solution to UPS downstream of the sonic line. These are an 8 deg sphere-cone in Mach 5, perfect gas, laminar flow at 0 and 4 deg angles of attack and the Reentry F body at Mach 20, 80,000 ft equilibrium gas conditions for 0 and 0.14 deg angles of attack. The results indicate that this procedure is a timely and accurate method for obtaining aerothermodynamic predictions on slender hypersonic vehicles.

THE MODELING OF COMPLEX CONTINUA: FUNDAMENTAL OBSTACLES AND GRAND CHALLENGES

Jan. 1993 19 p

(Contract DE-FG02-90ER-25084)

(DE93-006507; DOE/ER/25084-3) Avail: CASI HC A03/MF A01

The research is divided into the following areas: discontinuities and adaptive computation, chaotic flows, dispersion of flow in porous media, and nonlinear waves and nonlinear materials. The research program has emphasized innovative computation and theory. The approach depends on abstracting mathematical concepts and computational methods from individual applications to a wide range of problems involving complex continua. The generic difficulties in the modeling of continua that guide this abstraction are multiple length and time scales, microstructures (bubbles, droplets, vortices, crystal defects), and chaotic or random phenomena described by a statistical formulation. FLOW VISUALIZATIONS OF PERPENDICULAR BLADE VORTEX INTERACTIONS Semiannual Progress Report

Michael C. Rife and William J. Davenport 15 Oct. 1992 94 p

(Grant NAG1-1119)

(NASA-CR-192725; NAS 1.26:192725) Avail: CASI HC A05/MF A01

Helium bubble flow visualizations have been performed to study

perpendicular interaction of a turbulent trailing vortex and a rectangular wing in the Virginia Tech Stability Tunnel. Many combinations of vortex strength, vortex-blade separation (Z(sub s)) and blade angle of attack were studied. Photographs of representative cases are presented. A range of phenomena were observed. For Z(sub s) greater than a few percent chord the vortex is deflected as it passes the blade under the influence of the local streamline curvature and its image in the blade. Initially the interaction appears to have no influence on the core. Downstream, however, the vortex core begins to diffuse and grow, presumably as a consequence of its interaction with the blade wake. The magnitude of these effects increases with reduction in Z(sub s). For Z(sub s) near zero the form of the interaction changes and becomes dependent on the vortex strength. For lower strengths the vortex appears to split into two filaments on the leading edge of the blade, one passing on the pressure and one passing on the suction side. At higher strengths the vortex bursts in the vicinity of the leading edge. In either case the core of its remnants then rapidly diffuse with distance downstream. Increase in Reynolds number did not qualitatively affect the flow apart from decreasing the amplitude of the small low-frequency wandering motions of the vortex. Changes in wing tip geometry and boundary layer trip had very little effect. Author

TWO-PHASE/TWO-PHASE HEAT EXCHANGER ANALYSIS Final Report

Rhyn H. Kim Nov. 1992 19 p

(Grant NAG5-1503)

(NASA-CR-192783; NAS 1.26:192783) Avail: CASI HC A03/MF A01

A capillary pumped loop (CPL) system with a condenser linked to a double two-phase heat exchanger is analyzed numerically to simulate the performance of the system from different starting conditions to a steady state condition based on a simplified model. Results of the investigation are compared with those of similar apparatus available in the Space Station applications of the CPL system with a double two-phase heat exchanger. Author

AN INVESTIGATION OF LASER VELOCIMETRY MEASUREMENTS WITHIN HIGH SPEED, COMPLEX FLOWS Ph.D. Thesis

Mark S. Maurice 1992 212 p

Avail: Univ. Microfilms Order No. DA9239537

Laser velocimetry (LV) is a nonintrusive, optical method that measures particle velocities within a flow. Therefore, if LV measurements are to represent the structure of a flowfield, the particles must follow the dynamic motion of the fluid. However, in high speed, complex flows, the lag in particle response to fluid gradients can be substantial. In order to quantify velocity lag bias in high speed, mean velocity measurements, several flowfields are investigated experimentally and computationally. From measurements within the vortical flowfield of a supersonic delta wing at Mach 1.9, and for expansion flows at Mach 5.76, it is found that by coupling a particle equation of motion with the computational flowfield solutions, particle trajectories and velocity lag within complex flows can be predicted. For two primary flow structures, potential vortices and two-dimensional ideal shocks, it is found that relaxation distances can be quantified in terms of three dimensionless parameters. Results for these cases are presented graphically as an aid for test design and data analysis over a wide range of conditions. However, any analysis of velocity lag bias requires knowledge of the particle size distribution, which is often unknown in high speed flows. For a ten degree half-angle wedge at Mach Three, a methodology is presented which determines the mean particle diameter from measurements downstream of the shock, and then examines the remaining LV data throughout the flow. To extend this approach to flows with highly polydispersed particle sizes, an algorithm is developed which extracts the size distribution from the shape of LV velocity histograms. This method is applied to the investigation of a hypersonic inlet at Mach 5.76. Results show that despite the problem of velocity lag, measurements can still be used for computational code validation. In this final case, the developing boundary layer along the inlet ramp is accurately predicted, but the algebraic eddy viscosity model overestimates the turbulence production at the shock wave - boundary layer interactions. ASSESSMENT OF CLOSURE COEFFICIENTS FOR COMPRESSIBLE-FLOW TURBULENCE MODELS

P. G. Huang (Eloret Corp., Palo Alto, CA.), P. Bradshaw (Stanford Univ., CA.), and T. J. Coakley Oct. 1992 15 p

(RTOP 505-59-53)

(NASA-TM-103882; A-91212; NAS 1.15:103882) Avail: CASI HC A03/MF A01

A critical assessment is made of the closure coefficients used for turbulence length scale in existing models of the transport equation, with reference to the extension of these models to compressible flow. It is shown that to satisfy the compressible 'law of the wall', the model coefficients must actually be functions of density gradients. The magnitude of the errors that result from neglecting this dependence on density varies with the variable used to specify the length scale. Among the models investigated, the k-omega model yields the best performance, although it is not completely free from errors associated with density terms. Models designed to reduce the density-gradient effect to an insignificant level are proposed. Author

SHOCK TUBE APPLICATION TO THE STUDY OF COMPRESSIBLE TURBULENT BOUNDARY LAYER WITH MASS INJECTION Ph.D. Thesis

Jiunn-Yih Liaw 1992 109 p

Avail: Univ. Microfilms Order No. DA9302240

The dissertation explores the feasibility of using the shock tube in studying the heat transfer in the compressible turbulent boundary layer with mass injection. The flow under consideration is the asymptotically steady region induced behind the shock wave. The test model is a flat plate with a 2-D 30 deg slot. The shock-induced flow was computed numerically for both the quasi-steady and the asymptotically steady region. The results were presented in a x-t diagram to estimate the available testing time in a steady state sense. The injection flow was measured by using the slot as a flow measuring device. Heat transfer data were measured by using the thin-film heat gauges. Some preliminary heat transfer data were obtained at the flow Mach number 0.9, gas-to-wall temperature ratio 1.6, and Reynolds number 4.62 x 10(exp 7) (per meter). The data upstream of the slot, through slightly lower, agree with existing theory within measurement uncertainty. The data downstream of the slot were compared with other sets of data obtained at flow Mach numbers 0.03 and 0.55. This comparison reveals a possible Mach number effect on film-cooling. An attempt was made by using the Prandtl-Glauert formula to model this effect. More experimental data and further analysis are needed to confirm this finding. Final remarks will discuss the feasibility and propose further improvements based on the experience learned from this study. Dissert. Abstr.

DIRECT SOLUTIONS OF THE NAVIER-STOKES EQUATIONS WITH APPLICATION TO STATIC AEROELASTICITY Ph.D. Thesis

Fort Fraser Felker 1992 146 p

Avail: Univ. Microfilms Order No. DA9234093

A method was developed to directly calculate solutions to the steady, compressible, Navier-Stokes equations. Direct solutions do not involve an advance in time of an unsteady analysis, and neither time nor any 'time-like' variable appears in the system. The steady Navier-Stokes equations were discretized in space, and the resulting nonlinear system of algebraic equations was solved using Newton's method. The method exhibits rapid convergence, with the residual reduced to machine zero in approximately ten iterations. One of the benefits of this solution method is that it is straightforward to include the effects of other physical phenomena on the fluid dynamics, and the effects of the fluid dynamics on the other phenomena. As an illustration of this, the direct solution method was extended to calculate the steady flow about a flexible body. The shape of the body depends on the fluid flow, and the fluid flow depends upon the shape of the body. There is no iteration between separate fluid dynamics and structures analyses. Rather, the solution for the complete aeroelastic system is found using the direct solution technique. The techniques used in the direct solution method, and the fluid/structure coupling are described. Important issues which arose during the implementation of the method, and their resolution, are reviewed. Sample calculations are presented for several two-dimensional, transonic, convergent-divergent nozzles, both with

rigid and flexible walls. These calculations serve to illustrate the accuracy and efficiency of the direct solution method. Recommendations are provided for the directions of future research in this area. Dissert. Abstr.

THE STEADY NAVIER-STOKES PROBLEM FOR LOW REYNOLDS NUMBER VISCOUS JETS Ph.D. Thesis
Huakang Chang 1991 81 p
Avail: Univ. Microfilms Order No. DANN69767

The classical existence theorem for the steady Navier-Stokes equations, based on a bound for the solution's Dirichlet integral, provides little qualitative information about the solution. In particular, if a domain is unbounded, it is not evident that the solutions will be unique even when the data are small. Inspired by the works of Odqvist for the interior problem and of Finn for the problem of flow past an obstacle, we give a potential theoretic construction of a solution of the steady Navier-Stokes equations in several domains with noncompact boundaries. We begin by studying a scalar quasilinear elliptic problem in a half space, which serves as a model problem for the development of some of the methods which are later applied to the Navier-Stokes equations. Then, we consider Navier-Stokes flow in a half space, modeling such phenomena as a juet emanating from a wall, with prescribed boundary values. The solution which is obtained decays like /x/(exp -2) at infinity and has a finite Dirichlet integral. Finally, we solve the problem of flow through an aperture in a wall between two half spaces, with a prescribed net flux through the aperture, or with a prescribed pressure drop between the two half space. A steady solution is constructed which decays like /x/(exp -2) at infinity. For small data, uniqueness is proven with the class of functions which decay like /x/(exp -1) at infinity and have finite Dirichlet integrals. Dissert. Abstr.

AN EXPERIMENTAL STUDY OF THE SOURCES OF FLUCTUATING PRESSURE LOADS BENEATH SWEPT SHOCK/BOUNDARY-LAYER INTERACTIONS Final Technical Report, 1 Jan. 1990 - 31 Dec. 1992
G. S. Settles and S. Garg Apr. 1993 34 p
(Grant NAG1-1070)
(NASA-CR-192918; NAS 1.26:192918; PSGDL-R-92/93-0002) Avail: CASI HC A03/MF A01

An experimental research program providing basic knowledge and establishing a database on the fluctuating pressure loads produced on aerodynamic surfaces beneath three dimensional shock wave/boundary layer interactions is described. Such loads constitute a fundamental problem of critical concern to future supersonic and hypersonic flight vehicles. A turbulent boundary layer on a flat plate is subjected to interactions with swept planar shock waves generated by sharp fins at angle of attack. Fin angles from 10 to 20 deg at freestream Mach numbers of 3 and 4 produce a variety of interaction strengths from weak to very strong. Miniature Kulite pressure transducers flush-mounted in the flat plate are used to measure interaction-induced wall pressure fluctuations. The distributions of properties of the pressure fluctuations, such as their ring levels, amplitude distributions, and power spectra, are also determined. Measurements were made for the first time in the aft regions of these interactions, revealing fluctuating pressure levels as high as 160 dB. These fluctuations are dominated by low frequency (0-5 kHz) signals. The maximum ring levels in the interactions show an increasing trend with increasing interaction strength. On the other hand, the maximum ring levels in the forward portion of the interactions decrease linearly with increasing interaction sweep back. These ring pressure distributions and spectra are correlated with the features of the interaction flowfield. The unsteadiness of the off-surface flowfield is studied using a new, non-intrusive technique based on the shadow graph method. The results indicate that the entire lambda-shock structure generated by the interaction undergoes relatively low-frequency oscillations. Some regions where particularly strong fluctuations are generated were identified. Fluctuating pressure measurements are also made along the line of symmetry of an axisymmetric jet impinging upon a flat plate at an angle. This flow was chosen as a simple analog to the impinging jet region found in the rear portion of the shock wave/boundary layer interactions under study. It is found that a sharp peak in ring pressure level exists at or near the mean stagnation point. It is suggested that the phenomena responsible for this peak may be active in the swept interactions as well, and may cause the extremely high fluctuating pressures observed in the impinging jet region in the present experimental program. TRACKING SHARP INTERFACE OF TWO FLUIDS BY THE CIP (CUBIC-INTERPOLATED PROPAGATION) SCHEME
T. Yabe (Gunma Univ., Japan.) and F. Xiao (Gunma Univ., Japan.) 6 Jan. 1993 19 p Submitted for publication
(NIFS-206) Avail: CASI HC A03/MF A01

A method to treat a sharp discontinuity by the density function is proposed. The surface of the density function is described by one grid throughout the calculation even when the surface is largely distorted. This description is made possible by the CIP method combined with variable transformation. This scheme is applied to the linear wave propagation in one- and two-dimensions. In the nonlinear case, the injection of heavier fluid into lighter fluid is calculated and the winding of mushroom structure is successfully treated by the density function. Author (revised)

CONSEQUENCES OF SPONTANEOUS AND ANOMALOUS SYMMETRY BREAKING FOR THE ORBITAL AND MASS FLOW HYDRODYNAMICS OF He-3 - A Ph.D. Thesis
Frank Paul Gaitan 1992 119 p
Avail: Univ. Microfilms Order No. DA9305531

In this thesis we address three problems associated with the mass flow and orbital hydrodynamics of He-3 - A. The first concerns the form of the T = 0 mass current in local equilibrium; the second is a paradox associated with the non-conservation of superfluid linear momentum at T = 0; and the third involves a longstanding disagreement between past calculations of the intrinsic angular momentum in He-3 - A. These problems are more fully described in chapter 1 along with a brief review of the generalized Hartree-Fock approach to the Bardeen-Cooper-Schrieffer theory of superconductivity. In chapter 2 we describe our formulation of the quasiparticle dynamics. In chapter 3 we demonstrate the occurrence of anomalous symmetry breaking in He-3 - A, and in chapter 4 we see how the first two problems can be understood as consequences of this anomalous symmetry breaking. In chapter 5 we calculate the intrinsic orbital angular momentum via a Berry phase argument and also through a calculation that is careful to account for backflow currents which are necessary for the maintenance of particle number conservation in the superfluid phase. On the basis of the latter calculation we propose an explanation for the disagreement in past calculations of the intrinsic orbital angular momentum in He-3 - A. Dissert. Abstr.

MEASUREMENT OF VELOCITIES IN GAS-LIQUID TWO-PHASE FLOW USING LASER DOPPLER VELOCIMETRY
P. F. Vassallo, T. A. Trabold, W. E. Moore, and G. J. Kirouac Sep. 1992 29 p
(Contract DE-AC12-76SN-00052)
(DE93-008083; KAPL-4738) Avail: CASI HC A03/MF A01

Measurements of bubble and liquid velocities in two-phase flow were made using a new forward/backward scattering Laser Doppler Velocimetry (LDV) technique. This work was performed in a 6.4 by 11.1 mm vertical duct using known air/water mixtures. A standard LDV fiber optic probe was used to measure the bubble velocity, using direct backscattered light. A retro-reflector and lens assembly permitted the same probe to measure the liquid velocity with direct forward-scattered light. The bubble velocity was confirmed by independent measurements with a high-speed video system. The liquid velocity was confirmed by demonstrating the dominance of the liquid seed data rate in the forward-scatter measurement. Experimental data are presented to demonstrate the accuracy of the technique for a wide range of flow conditions, from bubbles as small as 0.75-mm-diam to slugs as large as 10-mm wide by 30-mm long. In the slug regime, the LDV technique performed velocity measurements for both phases, for void fractions up to 50 percent, which was the upper limit of our experimental investigation. DOE

PREDICTIVE MODELING OF PARTICLE-LADEN, TURBULENT FLOWS Quarterly Progress Report No. 1, 1 Sep. - 1 Dec. 1992

J. L. Sinclair 1992 18 p
(Contract DE-FG22-92PC-92540)
(DE93-008208; DOE/PC-92540/T1) Avail: CASI HC A03/MF A01

The successful prediction of particle-laden, turbulent flows relies heavily on the representation of turbulence in the gas phase. Several types of turbulence models for single-phase gas flow have been developed which compare reasonably well with experimental data. A low-Reynolds k-epsilon, closure model is chosen to describe the Reynolds stresses associated with gas-phase turbulence. This closure scheme, which involves transport equations for the turbulent kinetic energy and its dissipation rate, is valid in the turbulent core as well as the viscous sublayer. Several versions of the low-Reynolds k-epsilon closure are documented in the literature. However, even those models which are similar in theory often differ considerably in their quantitative and qualitative predictions, making the selection of such a model a difficult task. The purpose of this progress report is to document findings on the performance of ten different versions of the low-Reynolds k-epsilon model on predicting fully developed pipe flow. The predictions are compared with the experimental data. With the exception of the model put forth by Hoffman (1975), the predictions of all the closures show reasonable agreement for the mean velocity profile. However, important quantitative differences exist for the turbulent kinetic energy profile. In addition, the predicted eddy viscosity profile and the wall-region profile of the turbulent kinetic energy dissipation rate exhibit both quantitative and qualitative differences. An effort to extend the present comparisons to include experimental measurements of other researchers is recommended in order to further evaluate the performance of the models.

DATA PARALLEL FINITE ELEMENT TECHNIQUES FOR LARGE-SCALE COMPUTATIONAL FLUID DYNAMICS Ph.D. Thesis
Zdenek Johan 1992 108 p
Avail: Univ. Microfilms Order No. DA9302226

The objective of this work is to address two major issues arising in the computation of large-scale flow problems: storage and computing cost. A Galerkin/least-squares finite element formulation is used to solve the compressible Navier-Stokes equations. Structural heating is also considered by performing a classical Galerkin finite element discretization and by having a fully implicit coupling with the fluid. A matrix free implicit iterative solver based on the Generalized Minimal Residual Algorithm (GMRES) is developed to solve the nonlinear system of equations arising from the finite element discretizations. It is shown that the performance of this solver compares favorably with traditional implicit iterative techniques while reducing substantially the memory requirements. The computing cost issue is addressed through a data parallel implementation of the finite element solver on the Connection Machine massively parallel computers. A blocking strategy is presented to facilitate the handling of several element types in the same mesh. Two communication algorithms performing the gather and scatter operations required by the finite element implementation are proposed. The first algorithm makes use of communication primitives available in the Connection Machine Scientific Software Library. The second algorithm preserves data locality by partitioning the mesh using a parallel implementation of the spectral partitioning algorithm. The mesh decomposition leads to a reduction in the amount of data to be communicated between processing nodes. Fluid-structural heating interaction problems and compressible flow problems using meshes with close to one million elements, such as flow over a complete airplane, demonstrate the efficiency of the data parallel computing and communication strategies.

A COMPACT HIGH-ORDER EULER SOLVER FOR UNSTRUCTURED GRIDS Ph.D. Thesis
David W. Halt 1992 151 p
Avail: Univ. Microfilms Order No. DA9235899

A compact high-order scheme is developed for solving the Euler equations in two or three dimensions. The flow domain is discretized by triangles in 2D or tetrahedra in 3D. A novel scheme is introduced which implements a set of characteristic-based split-flux formulas along the element boundaries in a conservation framework. Polynomials of order 0 through 3 are used in each cell to represent the conservation flow variables. Solutions are demonstrated to achieve up to fourth order accuracy. Comparisons are shown for a variety of flow applications with other numerical results, wind tunnel data, and an analytical solution. Numerical results demonstrate a substantial gain in efficiency using compact higher-order elements over the lower-order elements.

NUMERICAL SIMULATION OF A SHOCK WAVE/TURBULENT BOUNDARY LAYER INTERACTION IN A DUCT Ph.D. Thesis
Wei-Li Yang 1992 219 p
Avail: Univ. Microfilms Order No. DA9236308

A numerical investigation of the interaction of an incident oblique shock wave with a turbulent duct flow is presented. The investigation consisted of solving the three dimensional, unsteady, compressible, and mass averaged Navier-Stokes equations. An implicit finite volume lower-upper time marching code (RPLUS) has been employed and modified. A three dimensional Baldwin-Lomax turbulence model has been programmed in conjunction with the code. Computed results are obtained at Mach number 2.9 for a turning angle of 12.99 degrees and Reynolds number based on duct width of 1.36 x 10(exp 7). Under various inlet conditions, the results clearly depict the flow characteristics including the shock structure, the separated flow region, the wall pressure distribution, and the skin friction distribution. The findings provide a physical understanding of the three dimensional vortex structure of the flow in a duct in which a shock wave interacts with a turbulent boundary layer. The results show that the ratio of the boundary layer thickness to the duct width is the critical parameter in determining the separation structure. The computational results also show that the corner vortices and center separation structures are closely related. However, the non-uniformities and secondary flows in the approach boundary layer do not change the separation structure qualitatively.

COMBINING PARTICLES AND WAVES FOR FLUID ANIMATION Ph.D. Thesis
Mark Hall 1992 80 p
Avail: Univ. Microfilms Order No. DA9234390

Modeling fluid motion is a problem largely unsolved by traditional modeling techniques. Animation of fluid motion has been possible only in special cases, falling into one of two general categories. Upper surface representations model wave phenomena for fluid in placid situations, such as calm ocean waves. Particle systems define the chaotic motion of fluid in highly volatile states, like waterfalls. Each technique can mimic physical motion of liquid only in limited situations. We propose a system unifying previous techniques. We describe a system containing fluid of both categories. Two representations for fluid, corresponding to previous methods, allow modeling a wide range of situations. Automatic transitions between representations allow using the most appropriate technique for a given physical situation. Fluid is represented by two types of primitives: drops and pools. The drops constitute a particle system describing small, independent components. Pools model large bodies of fluid in more placid situations. The notion of support differentiates the situations that each representation models best. In general terms, fluid is supported when there is a solid underneath the fluid. Previous techniques generally either assume that support is omnipresent or that support is nonexistent. In our system, support determines which representation should be used and when transitions between the two should occur. Supported drops flatten and become pools. Unsupported pools spawn drops. Combining the two techniques into a single system allows mimicking fluid in a broader range of physical situations than previous methods. The resulting system models fluid motion based on physical properties of the environment. Gravity causes fluid to fall or flow downward. Solids restrict fluid motion, changing the course of flowing fluid and defining the shape of contained fluid.

SOME NEW RESULTS FOR SOLVING LINEAR SYSTEMS ARISING FROM COMPUTATIONAL FLUID DYNAMICS PROBLEMS Ph.D. Thesis
Gang Lou 1992 149 p
Avail: Univ. Microfilms Order No. DA9236525

In this thesis, we consider the numerical solution of four kinds of linear systems: saddle-point problems, Stokes problems, symmetric systems (positive definite or indefinite), and unsymmetric systems. These systems

are related, and all of them arise from the numerical solution of partial differential equations. For saddle-point problems, we introduce a class of expansion methods based on new solution representation of the general problem. Many difficult computations involved in Uzawa and projection type methods for saddle-point problems are avoided in our approach. For the Stokes problems, by introducing a new variable, we split the linear system into several smaller systems according to its sparse structure. This new variable is then updated so that the split systems eventually produce the solution of the original problem. For symmetric systems that are indefinite and do not have a special sparse structure like saddle-point problems, we propose a class of nested iterative methods to handle them. We study how the convergence rate of the outer iteration is related to the convergence rate of the inner iterations. For symmetric positive definite systems, we propose a class of nested preconditioners and analyze properties of these preconditioners. Some necessary and sufficient conditions for the optimality of these nested preconditioners are established. Finally, for unsymmetric systems, we generalize the concept of spectral equivalence for symmetric positive definite systems to these general systems, We also study some properties of spectrally equivalent matrices and consider their applications for constructing efficient iterative methods. VORTEX SHEDDING IN OSCILLATORY FLOW Ph.D. Thesis
Khalfan Al-Asmi 1992 316 p
Avail: Univ. Microfilms Order No.BRDX98100

Measurements of the response to inline flow oscillations of vortex shedding from certain bluff bodies were made. Four cylinders with fixed separation points were exposed to a mean stream with controlled sinusoidal oscillations at defined frequency ratios and amplitudes. Attention was concentrated on the highly sensitive reduced velocity regime around the inverse of twice the Strouhal number, 1/2S. Synchronization of vortex formation was first established; then, for conditions at which synchronization occurred, threshold amplitude was measured. In order to determine the common and distinguishing features of bluff body shape the response from cylinders having 'zero' and finite after body were investigated. Finally, for a selected cylinder, the influence, in the presence of oscillations, of turbulence intensity (of defined scale), solid blockage, and aspect ratio to the synchronous range were examined. It was found that amplitudes of oscillations of the order of 0.025 were sufficient to induce frequency lock-in when the reduce velocity was close to 1/2S and, provided the amplitude was sufficiently large, limited synchronization could also be induced near the upper and lower reduce velocities of 1/S and 1/4S. Synchronization is accompanied by enhanced vortex shedding which, in turn, can lead to increased base suction (and therefore increase in drag force). Flow visualization revealed that the near wake vortex arrangement can vary a great deal depending on the ratio of Strouhal numbers at the forced and self-excited frequencies (N/n(sub o)). It was concluded that the behavior of the base pressure reflected this situation and that the range of synchronization depended strongly on the stability of the prevailing mode of vortex shedding. The precise details of the flow were found to be highly dependent on body geometry and the frequency ratio N/n(sub o). In the smaller tunnel, having a working section size of 0.3 x 0.3 m, it was possible to produce sinusoidal variations of the working section flow, having peak to peak amplitude of up to 60 percent of the mean flow speed and frequencies up to, typically, that corresponding to the acoustic quarter-wavelength frequency determined by the tunnel length. Over the viable working range, the device is shown to produce high quality periodic flow with negligible harmonic distortion or acoustic noise difficulties.

NUMERICAL SIMULATION OF TIME-DEPENDENT THERMOCAPILLARY CONVECTION IN LAYERED FLUID SYSTEMS Ph.D. Thesis
Leonard Joel Peltier 1992 271 p
Avail: Univ. Microfilms Order No. DA9304596

Time-dependent thermocapillary convection in single and encapsulated fluid layers is considered. Through a parametric study of thermocapillary convection in a single layer of a Prandtl number 6.78 fluid, a thermal-convective mechanism for oscillatory thermocapillary convection is explored. The instability is shown to depend upon temporal coupling between large scale thermal structures within the flow field and the temperature sensitive free surface. This interaction is initiated by cooling of the free surface from below by a cool finger of fluid convected from the cold wall beneath the large central eddy. A primary result is the development of a stability diagram for the Cartesian thermocapillary system presenting the critical Marangoni number separating steady from the time-dependent flow states as a function of aspect ratio for the range of values between 2.3 and 3.8. A minimum critical aspect ratio near 2.3 and a minimum Marangoni number near 2000 are predicted. Below these critical parameters, steady convection is found within the parameter ranges investigated. Extension of this work to encapsulated systems of moderate Prandtl number fluids targets both (1) water encapsulation of Fluorinert FC-75 and (2) ethylene glycol encapsulated by FC-75 from below and hexadecane from above. Particular attention is focused on modes of time-dependence and on the implications of using Antonow's Rule to predict the thermal coefficient of interface tension from surface tension data. The primary findings are that similar mechanisms for time-dependent thermocapillary convection exist for single layer and encapsulated layer fluid systems, gravity has a stabilizing influence on buoyant/thermocapillary convection with respect to time-dependence up to the transition from steady to time-dependent buoyancy driven convection, shear effects at a thermocapillary interface may reduce convection in the encapsulated fluid layer, and the absence of reliable data on the thermal coefficients of interface tension is a primary impediment to simulations of targeted fluid systems. The computer program developed for this work integrates the two-dimensional, time-dependent Navier-Stokes equations and the energy equation by a time-accurate method on a stretched, staggered mesh. Flat free surfaces and fluid/fluid interfaces are assumed.

LIQUID SURFACE BREAKUP OF NONTURBULENT AND TURBULENT LIQUIDS Ph.D. Thesis
Pei-Kuan Wu 1992 157 p
Avail: Univ. Microfilms Order No. DA9303841

An experimental study of the primary breakup in the near-injector region of large diameter (3.6-9.5 mm) liquid jets in still gases is described. The experiments involve the injection of different test liquids at a variety of velocities into various gas environments, with slug flow and fully-developed turbulent pipe flow at the jet exit. Measurements included flash photography, pulsed shadowgraphy, and single- and double-pulse holography. Drop sizes after primary breakup were found to satisfy Simmons' universal root-normal distribution with the ratio of the mass median diameter (MMD) and Sauter mean diameter (SMD), MMD/SMD = 1.2; therefore, the drop size distribution can be characterized solely by the SMD. For nonturbulent primary breakup, the SMD increased with distance from the jet exit and then remained nearly constant within a fully-developed primary breakup regime. SMD measurements in the fully-developed regime did not agree with existing unstable wave growth theories, however, the SMD could be correlated with an expression involving the thickness of an injector passage wall boundary layer at the jet exit. Drops formed by this primary breakup mechanism are intrinsically unstable to aerodynamic secondary breakup. When the liquid/gas density ratio is larger than 500, turbulent primary breakup is controlled by liquid properties alone and mass weighted streamwise and cross-stream drop velocities were comparable to mean streamwise and cross-stream rms fluctuating velocities in the liquid, respectively. The drop sizes at the onset of breakup could be correlated by comparing the surface tension work required to form a drop with the kinetic energy of radial velocity fluctuations. The SMD variation of turbulent primary breakup with distance from the jet exit could be correlated with a Rayleigh breakup mechanism which provides the time required to complete the drop detachment process from a liquid surface. When the liquid/gas density ratio was less than 500, aerodynamic effects affected turbulent primary breakup and final drop sizes were reduced by merging of turbulent primary breakup and aerodynamic secondary breakup; a good correlation of the final drop sizes due to this behavior was obtained by combining correlations for turbulent primary breakup and aerodynamic secondary breakup. ANNULAR FLOW ENHANCED TWO-PHASE EVAPORATIVE HEAT EXCHANGER FOR SPACE-BASED SYSTEMS Ph.D. Thesis
D. Nikanpour 1991 191 p
Avail: Univ. Microfilms Order No. BRDX98015

The development of multi-kilowatt space-based systems requires the

transport of waste heat loads over long distances in micro-gravity conditions. In this context two-phase heat transport systems are attractive enabling a high rate of heat transport with low pump powers compared to single phase systems. In this context the design of a two-phase heat exchanger to transfer heat from a single-phase fluid (water) to a two-phase fluid (Freon 114) is discussed. Until reliable micro-gravity (less than 10-3g) test data on the heat transfer and pressure drop in a two-phase flows are available, it is deemed necessary that the design of heat exchanger's passages should promote gravity-independent flow regimes. This would make the design and test data, obtained at ground conditions, applicable in micro-gravity environments. The design concept investigated hinges on utilizing a set of helical flow passages (with small cross sectional area) to ensure a predictable flow regime, annular flow, up to high vapor qualities (greater than 0.8), in both micro-gravity and one 'g' environments. The concept was applied to the design of a 5 kW helically coiled evaporative heat exchanger for space-based systems, which was subsequently manufactured and tested. Ground tests gave results close to analytical predictions based on computer simulations of the heat transfer and pressure drops in helical flow passages. Finally design guideline for a two-phase evaporative heat exchanger for space-based systems is provided, along with conclusions and areas to be further researched. Dissert. Abstr.

SPATIAL SIMULATION OF TRANSITION IN WALL-BOUNDED SHEAR FLOWS: ACTIVE CONTROL AND EFFECTS OF SURFACE ROUGHNESS Ph.D. Thesis
Gokhan Danabasoglu 1992 295 p
Avail: Univ. Microfilms Order No. DA9304550

Spatial numerical simulations of instabilities in wall-bounded shear flows are discussed. In the first part, secondary instability in a three-dimensional plane channel flow is investigated. Also studied is the applicability of active control by periodic suction blowing to suppress the instability waves. In the second part, the effects of a two-dimensional, isolated roughness element on the spatial evolution of disturbances in boundary layer flows are considered. The mathematical model incorporates the incompressible, time-dependent, three-dimensional, full Navier-Stokes equations. These equations are integrated on a nonstaggered mesh using a mixed finite difference/spectral method with a time-splitting technique which decouples the momentum and pressure equations. For the problems involving the roughness element, a multidomain solution procedure was developed. The computer programs are optimized for operation on the CRAY-2S and CRAY Y-MP. The comparisons of the numerical results with the parallel linear stability theory reveal excellent agreement showing that the scheme accurately captures the evolution of disturbances both in time and space. Computations are performed to detail the secondary instability of the plane channel flow revealing good agreement with the experimental investigations. A local energy transfer rate analysis for the relevant wave triads is also performed considering only the nonlinear terms, and it is shown that the Tollmien-Schlichting wave acts only as a catalyst in agreement with the previous theoretical studies and temporal numerical simulations. It is also found that active control by period suction blowing successfully attenuates instability waves even at high (non-linear) amplitudes, reducing disturbance amplitudes very significantly and delaying transition to turbulence. The upstream effects of the control wave is shown to be confined to a small region in the vicinity of the control slot and does not propagate upstream. Finally, boundary layer simulations with surface roughness conclusively show that frequencies which are in the shear (mixing) layer instability range (but, stable according to the parallel linear stability theory) have higher growth rates than the Tollmien-Schlichting frequencies when the roughness element is large. Hence, the stability of the separation zone behind the roughness element is governed by the stability of the shear layer at its edge.

THE INTERACTION OF MODULATED VORTEX PAIRS WITH A FREE SURFACE Ph.D. Thesis
Christian Ernst Willert 1992 190 p
Avail: Univ. Microfilms Order No. DA9303277

Spatially modulated vortex pairs were generated below a free surface by two counter-rotating flaps whose edges approximate a sinusoid. The surface interactions of the vertically approaching vortex pairs were visualized by the shadowgraph technique. For certain initial conditions each modulated vortex core was seen to form a line of circular surface depressions. Subsequent digital particle image velocimetry (DPIV) measurements of several vortex pair cross-sections and the subsurface plane confirmed the existence of vortex core terminations at the surface - the modulated vortex tube was broken into a line of U-vortices. A prerequisite for reconnection of the vortex with the surface is that the flow's kinematics force the vortex core, that is regions of high vorticity, toward the surface. The ensuing locally concentrated viscous flux of surface-parallel vorticity through the surface is balanced by a local surface deceleration. Surface-normal vorticity appears on either side of the decelerated region whose gradually increasing circulation is directly balanced by the loss of circulation of the surface-parallel vortex. The circulation transfer for the Re = Gamma/(pi nu) approx. equals 2000 vortex tube lasts approximately 1 second. However, shear forces caused by small amounts of surface contamination (surface active agents) and its associated subsurface boundary layer inhibit the reconnection process by preventing the essential viscous flux of parallel vorticity through the surface. This work makes extensive use of digital particle image velocimetry (DPIV) in obtaining instantaneous flow field information from two-dimensional spatial cuts through the flow domain. A large number of laser-sheet illuminated particles are imaged by a solid state sensor yielding image sequences of single-exposed particles. A local interrogation of a pair of consecutive images by means of a local two-dimensional cross-correlation extracts the average displacement of the sample particle images whose velocity is then inferred from the magnification factor and time difference between the particle illumination. The acquisition of image sequences gives insight to the temporal evolution of the images flow field. Although the image acquisition rate is limited to the 30 Hz video standard, asynchronous particle illumination in conjunction with a specially configured camera yield particle image pairs whose time difference is on the order of 2 milliseconds. AN EXPERIMENTAL STUDY OF PARTICLE-LADEN JET INTERACTIONS WITH COCURRENT FLOWS Ph.D. Thesis
Periasamy Chinnapalaniandi 1992 159 p
Avail. Univ. Microfilms Order No. DA9306096

The interactions of a particle laden jet with cocurrent flow was studied experimentally. To improve sorbent utilization an understanding of particle and fluid interaction within the turbulent mixing zone is necessary. To improve the understanding of this phenomenon, one needs to obtain measurements of the particle size, velocity, concentration, and gas phase velocity within the shear layer region of particle-laden jet. A particle injection test facility was designed specifically to study the interaction of particle laden jets using non-intrusive, laser-based optical techniques. Spherical glass particles in the size range of 2-100 micron were used. The mass loading was varied between 0 to 10. The Particle Dynamics Analyzer, which utilizes phase Doppler interferometry and laser Doppler anemometry was used for measuring the particle velocities, sizes, and concentration as well as gas phase velocities in the flow field. Phase discrimination between the particle phase and gas phase was accomplished by utilizing particle velocity and size statistics. Single phase, particle and gas phases mean velocities and fluctuating turbulent intensities, and concentration profiles were obtained. Single phase velocity measurements were used as baseline data for comparison with particle laden flows. The decay rate of mean gas phase centerline velocity for particle laden flows less than that for single phase flows. This resulted from the momentum transfer from particles to the gas phase. The axial and radial rms velocities of the particle and gas phases decrease with increase in mass loading. The spreading rate of particle laden jet is also reduced. This decrease resulted from the reduction in the radial fluctuating velocity. Entrainment increases with higher jet velocity and reduced mass loading. Higher mass loading reduces the turbulence level; therefore there is a reduction in mixing and entrainment. For the range of particle sizes used, larger particles tend to concentrate around the centerline of the jet. For a higher mass loading, the particles are concentrated in a smaller radial distance, and there is a resulting reduction in dispersion and mixing of particles. Dissert. Abstr.

NUMERICAL STUDY OF CAVITY NATURAL CONVECTION FLOW WITH AUGMENTING AND COUNTERACTING EFFECTS BY PROJECTION FINITE ELEMENT METHOD Ph.D. Thesis

Tswen-Chyuan Jue 1992 182 p
Avail: Univ. Microfilms Order No. DA9234421

A numerical study of natural convection in cavities under the effects of thermocapillarity and gravity modulation is conducted in this research. Three different algorithms which are first-order explicit, second-order Taylor-Galerkin and semi-implicit schemes based on the projection finite element method (FEM) are developed. Each algorithm presents its own characteristics and advantages. By considering the problem characteristics and computational efficiency, the semi-implicit method is a better choice for this research. In this thesis, the physical investgation of cavity natural convection with augmenting or counteracting effects is divided into four parts. At first, the cavity flow with buoyancy force and thermocapillary effect is studied for different Marangoni numbers and aspects ratios. Next, the Benard convection with gravity modulation effects in normal gravity and zero-g gravity is investigated. The natural convection flow exhibits dramatically different flow structure under the influence of different modulation directions and frequencies. In addition, the natural convection with combined thermocapillarity and gravity modulation is explored for different modulation directions, frequencies and Marangoni numbers. Finally, the cavity natural convection flow with a deformable free surface is analyzed for different Grashof numbers and Marangoni numbers. Results of this research show that the surface tension provides a strong influence in the natural convection flow in both normal gravity and microgravity states. Particularly, the low aspect ratio and microgravity environments favor the development of thermocapillary-driven flow. On the other hand, the existence of gravity modulation makes the flow field different from the constant gravity state by applying different modulation directions and frequencies. The simultaneous presence of thermocapillarity and g-jitter creates a dramatically different flow pattern when compared to the results without thermocapillary effect. When a deformable free surface is considered, the flow field and heat transfer rate at the corners of free surface are changed due to the deformation of free surface shape. Dissert. Abstr.

IMPLICIT MULTIGRID SOLUTION OF THE COMPRESSIBLE NAVIER-STOKES EQUATIONS WITH APPLICATION TO DISTRIBUTED PARALLEL PROCESSING Ph.D. Thesis
Thomas Lee Tysinger 1992 185 p
Avail: Univ. Microfilms Order No. DA9236051

Efficient numerical procedures are developed for the solution of the Navier-Stokes equations. The Navier-Stokes equations are a system of conservation laws which govern the motion of compressible, viscous, heat-conducting fluids. A conservative finite volume formulation is used for spatial discretization of the governing equations, resulting in a system of ordinary differential equations. To advance the system in time, an Alternating Direction Implicit (ADI) procedure suitable for the Navier-Stokes equations is developed. The resulting implicit system is diagonalized to improve the computational efficiency of the scheme. Viscous contributions are added to the scheme implicitly in a way that enhances the stability, yet does not disturb the efficiency of the algorithm. Rapid convergence to a steady state solution is achieved with a recursive multigrid algorithm. The stability and efficiency of the scheme are demonstrated with simulations of flow over wing sections. Furthermore, the algorithm has been implemented within the framework of multiple-block structured grids in which the spatial domain is decomposed into multiple blocks and the solution is advanced in parallel on the different blocks. Generic utilities have been developed to implement such a scheme in distributed computing environments. The multiple-block algorithm is designed so that the explicit residual calculation is identical to that of the single-block scheme, and therefore converged solutions for both schemes must be the same. To accelerate convergence, horizontal, vertical, and asynchronous multigrid algorithms are tested. Significant speedups have been achieved in a multiprocessor environment, while convergence rates similar to those of the single-clock schemes are observed. Dissert. Abstr.

DYNAMICS OF TURBULENT SLUGGING IN TRANSITIONAL PIPE FLOW Ph.D. Thesis
Joel Patrick Jenkinson 1992 318 p
Avail: Univ. Microfilms Order No. DA9235925

This dissertation examines the phenomenon of turbulent slugging (with particular focus on periodic slugging), a persistent type of transitional pipe flow. Turbulent slugging occurs either periodically or not. Which occurs is found to depend on the manner in which the flow is controlled; slugging is periodic when the pressure difference between the pipe inlet and exit is held constant, nonperiodic when Re(sub D) is held constant. In periodic slugging, deviations from exact periodicity--up to 5 percent of the mean period--are noted. These deviations are analyzed (in an effort to find chaos in an 'open' flow, using methods derived from information theory) and found to be nondeterministic. Turbulent slugs are the manifestation of a convective instability; systems having convective instabilities are often found to be noise driven, which is the case for nonperiodic slugging. For periodic slugging, the flow is 'closed' by strong feedback; the dynamics are intrinsic. Periodic slugging is analyzed as a dynamical system. Dimensionless pressure difference bar-(delta)P* is identified as the appropriate bifurcation parameter, Re(sub D)(t) and turbulent flow fraction Gamma(t) as dynamical variables, and pipe L/D as an auxiliary parameter. A bifurcation picture is constructed from experiments in a pipe with L/D = 1.181 x 10(exp 3). Experiments in which L/D is varied (from 1.17 x 10(exp 3) to 4.10 x 10(exp 3)) demonstrate that the slugging frequency is properly nondimensionalized as f(sub s)L/bar-U, not f(sub s)D/bar-U. A heuristic computer model which is quite successful in reproducing experimental results for periodic slugging is developed. The model is used to identify important or potentially important effects; in particular, comparisons of model and experimental results suggest the importance of bulk flow unsteadiness (acceleration/deceleration) on flow stability, transition, and turbulence production. The model is also used to examine effects of varying L/D, up to L/D is approximately 10(exp 6); an asymptotic range in bar-(delta)P* for periodic slugging is approached for L/D greater than 10(exp 4). Some preliminary results on effects of low-amplitude random and periodic forcing of bar-(delta)P* are also presented. In the latter case, only periodic and quasi-periodic (no chaotic) flows are found. Dissert. Abstr.

LAMINAR AND TURBULENT NATURAL CONVECTION HEAT TRANSFER IN TROMBE WALL CHANNELS Ph.D. Thesis
Tony D. T. Chen 1992 246 p
Avail: Univ. Microfilms Order No. DA9301142

The natural convective heat transfer and air movement in a Trombe wall solar passive system has been studied analytically and numerically. Three Trombe wall channel geometries including the parallel channel with axial inlet and exit, parallel channel with side vents and Trombe wall channel coupled to the room have been considered. For the parallel channel with axial inlet and exit geometry, a momentum-integral method has been used to solve parabolic governing equations for two dimensional laminar flow. This formulation leads to a second order ordinary differential equation for pressure defect in the Trombe wall channel. The solution of this equation leads to prediction of velocity, temperature and pressure fields, and Nusselt number correlations that are in good agreement with previously reported finite difference solution of natural convection boundary layer equations. For the side-vented channel case, results are obtained for both two dimensional laminar and turbulent natural convective flow regimes. Due to presence of recirculating flow patterns in this geometry, full Navier-Stokes equations in two-dimensions are employed. The turbulent flow characteristics are modeled by a two-equation (k-epsilon) model. The governing equations for steady laminar as well as turbulent flows are solved by a finite volume technique that uses the quadratic upwind differencing scheme to discretize non-linear governing equations to form algebraic equations which govern physical variables at the various numerical grid points. The coupled algebraic equations are solved by a semi-implicit algorithm known as SIMPLER. Flow patterns, isotherms and heat transfer characteristics are obtained for aspect ratios of 10 and 20, and Grashof number ranging from 1.4 x 10(exp 3) to 1.4 x 10(exp 8). The effect of the free pressure boundary location of flow characteristics is also analyzed. Results show that the mass flow rates induced and net energy delivered by the system is governed by the channel Grashof number and the channel vent size. The total vent loss coefficient for the side-vented cavity shows a minimum at Gr = 1.4 x 10(exp 4) for which the dimensionless mass flow rate also shows a maximum value. Dissert. Abstr.

THE EFFECTS OF LARGE-AMPLITUDE, LOW-FREQUENCY EXCITATION ON A THREE-DIMENSIONAL JET Ph.D. Thesis

Robert Bois Farrington 1992 874 p
Avail: Univ. Microfilms Order No. DA9304555

Large-amplitude, low-frequency excitation can increase the mixing and spreading in the two-dimensional region of a large aspect ratio slot jet and accelerate its transition from a two-dimensional form to an axisymmetric form. The average jet Reynolds number was 7240 and temperature differences were less than 10 C. A rotating damper was used to excite the flow at frequencies up to 56 Hz resulting in Strouhal numbers up to 0.32. Hot-wire anemometry was used to determine profiles of velocity and velocity fluctuations. Digital analysis of infrared images provided quantitative results on average spatial temperature distributions, temperature profiles, jet edge profiles, axial temperature decay rates, and mixing efficiencies. Large-amplitude, low-frequency excitation considerably distorts the velocity and velocity fluctuation profiles. Lower frequencies affect near-nozzle behavior and relatively higher frequencies affect the flow further from the nozzle. Decomposition of the temporal velocity profile into its phase-averaged mean, periodic, and random components show that most of the fluctuation is due to the periodic component with the random component contributing only 2 percent to 5 percent of the total velocity fluctuation. Depending on the excitation frequency, the half-harmonic and occasionally the quarter-harmonic can dominate the fundamental frequency. Higher excitation frequencies interact quickly with the flow structures generating multiple subharmonics and then dissipate while lower frequencies interact with structures near the nozzle exit without generating many subharmonics and then propagate with less interaction with flow structures. Excitation leads to increased velocity and temperature jet widths and accelerated decay of the centerline velocity and temperature. Infrared imaging shows that excitation does not distort the temperature profile as much as it does the velocity profile. Excitation enhanced the longitudinal 'saddle-back' profiles of the velocity and temperature. Both hot-wire anemometry and infrared imaging show that excitation accelerates the transformation of a rectangular jet to an axisymmetric form. Entrainment is not only increased in the two-dimensional regime but higher entrainment occurs sooner due to accelerated transformation to the axisymmetric regime, where entrainment increased linearly with distance rather than as the square root of the distance as in the two-dimensional regime. Dissert. Abstr.

THE INSTABILITY OF A LIQUID JET IN A COMPRESSIBLE AIRSTREAM Ph.D. Thesis
Hsi-Shang Li 1992 180 p
Avail: Univ. Microfilms Order No. DA9302442

The instability of a liquid jet in a coflowing compressible airstream has been studied, motivated by the experimentally observed surface wave phenomenon and breakup of a liquid jet injected transversely into a compressible gas flow. The linear stability analysis of a two-dimensional plane liquid jet in a compressible airstream is formulated first to correlate the instability characteristics with the compressibility of the airstream. The small-amplitude disturbances superimposed on the mean flow inside and outside the jet are governed by Laplace's equation and the convective wave equation, respectively, along with suitable boundary conditions at the interfaces. The conditions for a valid linearization of the convective wave equation are obtained. It is established that the transient motion of the gas can dominate so that the nonlinear term due to accumulation of disturbances in the basic flow can be negligible even as the Mach number approaches unity. The dispersion relation has been developed and studied for both temporally and spatially growing modes. A physical understanding of how compressibility affects the growth rate has been made clear by applying a 1D compressible continuity equation at the interface region and studying the convection and accumulation of vorticity. Furthermore, the kinetic energy of the disturbed liquid jet is examined to see how surface tension and airstream pressure transfer energy between the liquid jet and the compressible airstream. A similar linear study using a circular liquid jet model is then formulated in order to further investigate the behavior of the axisymmetric and non-axisymmetric unstable modes. The empirically obtained sonic point criterion for predicting jet breakup has been partially explained by studying both the maximum growth rates and the transition from convective instability to absolute instability near M approx. 1 as obtained through these linear instability analyses. Furthermore, numerical simulations of the interfacial instability of a 2D plane liquid jet and of an axisymmetrical circular liquid jet in a compressible airstream are performed to investigate the nonlinear aspects of these problems. A high resolution scheme which has second order accuracy in space and time is coupled with a Lagrangian marker particle algorithm to visualize the large scale motion of the interfaces in compressible flow. A numerical algorithm based on an approximate equation of state of a compressible liquid is developed to allow this two-fluid system to be governed by the nonlinear Euler equations in conservative form. The initial growth of small disturbances given by the simulations agrees well with the instability characteristics of the jet flow established by the linear theory. The process of the jet disruption in compressible flow involves the formation of spikes and the stretching and detachment of the liquid main center core. Dissert. Abstr.

ENERGY DISSIPATION IN INELASTIC FLOW OF COHESIONLESS GRANULAR MEDIA Ph.D. Thesis
Naoyuki Okada 1992 176 p
Avail: Univ. Microfilms Order No. DA9303271

In a granular mass which supports the externally applied loads through contact friction, the external work is partly stored and partly dissipated by friction or other mechanisms. In many applications involving relatively small pressures and hard granules, the dissipation by frictional sliding constitutes the major energy absorbing mechanism. Based on micromechanics, it is shown that the external work supplied to a water-saturated sand mass is mainly dissipated through friction between contacting granules. The frictional energy is formulated as a linear function of effective pressure. The model results are compared with the cyclic shearing experiments. A large hollow cylindrical torsional apparatus is used for the experiments, with sand as the test material. This thesis consists of three related parts. First, the results of a study of the cyclic shear deformation behavior under undrained conditions are presented. Experiments are conducted under strain-controlled conditions with various strain amplitudes. The relation between the excess pore water pressure and the corresponding external work in cyclic shearing is studied experimentally. Then, the results of a micromechanical model are compared with the experimental measurements. It is shown that the internal energy dissipation can be expressed as the history of the effective pressure and a single parameter. Second, the cyclic shear deformation behavior under drained conditions is studied. It is shown experimentally that the total volume decreases after each cycle, while the corresponding shear modulus increases. It is found that the energy dissipation coefficient is not constant in drained tests, but that these coefficients for undrained and drained tests approach each other as the number of cycles is increased. Third, the effect of the residual strain on the undrained cyclic shear deformation characteristics is experimentally studied. Experiments are conducted under both stress- and strain-controlled conditions, and the corresponding effects are investigated. It is shown that the shear deformation characteristics are significantly influenced by the residual strain under both strain- and stress-controlled conditions. In the stress-controlled tests, the shear resistance depends on the magnitude of residual strain. In the strain-controlled tests, however, the shear resistance does not seem to be strongly influenced by the magnitude of the residual strain. Dissert. Abstr.

STABILIZED FINITE ELEMENT METHODS FOR INCOMPRESSIBLE FLOWS WITH EMPHASIS ON MOVING BOUNDARIES AND INTERFACES Ph.D. Thesis
Marek Antoni Behr 1992 233 p
Avail: Univ. Microfilms Order No. DA9303369

Two finite element formulations for incompressible fluid dynamics are presented. The space-time velocity-pressure formulation is used for flow problems involving moving boundaries and interfaces. The formulation is based on a time-discontinuous Galerkin method, supplemented with least-squares-type stabilization terms. The discussion centers on the application of the method to various problems with deforming domains. In particular, the formulation is employed to simulate three-dimensional sloshing in a storage tank subjected to external vibrations. The stress-velocity-pressure formulation is developed, essentially for viscoelastic flows. Treatment of stress as a separate unknown allows for inclusion of complex constitutive relations. Least-squares-type stabilization terms provide, once more, robustness to otherwise potentially unstable formulation. The method is first tested on Newtonian fluid flows past a circular cylinder in two dimensions. Then, by using simple viscoelastic constitutive model, the formulation is applied to a standard test problem. The strategies for the

solution of large systems of equations arising from the finite element discretization of the above formulations are also discussed. Particular emphasis is placed on iterative methods and the implementations on massively parallel supercomputers, paving the way for solving very large-scale practical problems, including those in three dimensions.

ASYMPTOTIC STUDIES OF GRAVITY-DRIVEN REACTING COATING FLOWS AND PULTRUSION PROCESSES Ph.D. Thesis
Quan Qi 1992 242 p
Avail: Univ. Microfilms Order No. DA9305658

Coating flows have many very important applications in engineering. The first part of this thesis deals with gravity-driven reacting coating flows down an inclined plane. When the reaction activation energy is large and heat release is significant, long wave theory and large activation energy asymptotics are applied jointly to derive a consistent set of governing equations, which describe wave formation on the free surface and evolution of the reaction front. The key feature shown by the solution is the coupling of the free surface with the reaction front. When the reaction activation energy is small and heat release is insignificant, long wave theory leads to a single governing equation for wave formation on the free surface. Unlike its traditional counterpart, this equation has variable coefficients attributed to the effect of variable viscosity. The solution of this equation shows that linear, as well as, nonlinear wave formations differ appreciably from the constant viscosity coating flows. Pultrusion is a composite manufacturing process. Issues such as variable viscosity resin flows etc., are examined in the second part of this thesis. Dissert. Abstr.

COMPUTATIONAL MODELLING OF 3D FLOW IN COMPLEX DUCTS AND PASSAGES Ph.D. Thesis
Fue-Sang Lien 1992 557 p
Avail: Univ. Microfilms Order No. BRD-97662

A computational procedure has been developed for predicting separated turbulent flows in complex two-dimensional and three-dimensional geometries. The procedure is based on the fully conservative, structured finite volume framework, within which the volume are non-orthogonal and collocated such that all discrete fields of flow variables are stored at one and the same set of nodes. To ease the task of discretization and to enhance the conservative property of the scheme, a Cartesian decomposition of the velocity field has been used, rather than a contravariant, coordinated directed decomposition. As an alternative, an adaptive decomposition has also been included, in which one velocity component is allowed to adapt itself to a pre-defined, essentially arbitrary datum line, with the other two components normal to that adapted. This latter decomposition has been provided with the view to the procedure being preferentially applied to curved three-dimensional duct of variable cross-sectional area. The solution algorithm is iterative in nature, approaching the steady-state solution by a sequential solution for velocity components and pressure with the aid of a pressure-correction algorithm. Convection is approximated with a range of schemes, among them first-order, second-order and third-order upstream-weighted schemes, and with a Total Variation Diminishing MUSCL scheme, the last applied specifically to transport equations governing turbulence properties. A broad range of flows, totalling some 20 configurations, have been computed within an extensive validation exercise, encompassing inviscid, laminar and turbulent flows, both compressible and incompressible, some two-dimensional and others three-dimensional. A number of geometries have been computed principally in order to verify or examine the adequacy of numerical practices or the performance of the multigrid convergence acceleration scheme. Many, however, involve the investigation of turbulence-model performance by reference to detailed experimental results. Among the most challenging flows computed are: shock-induced separation over bumps, computed with second-moment closure; separated flow through a sinusoidal constriction, also computed with second-moment closure; and three-dimensional flow through a S-shaped diffuser calculated with low-Reynolds-number models. Dissert. Abstr.

HEAT TRANSFER MEASUREMENTS IN SWEPT SHOCK WAVE/TURBULENT BOUNDARY-LAYER INTERACTIONS Ph.D. Thesis
Yeol Lee 1992 187 p
Avail: Univ. Microfilms Order No. DA9236860

An experimental research program providing basic knowledge and establishing a database on the heat transfer in three-dimensional shock wave/boundary-layer interaction is described. High thermal loading in such interactions constitutes a fundamental problem of critical concern to future supersonic and hypersonic flight vehicles. A turbulent boundary-layer on a flat plate is subjected to interactions with swept planar shock waves generated by a sharp fin. Fin angles from 10 deg to 20 deg at freestream Mach numbers 3.0 and 4.0 produce a variety of interaction strengths from weak to very strong. A foil heater generates a uniform heat flux over the surface of interest and thin-film resistance thermometers mounted on it are used to measure the local surface temperature. The heat convection equation is then used to calculate the local heat transfer coefficients. The present heat transfer technique is applied to measure heat transfer distributions for 5 different interaction cases. The experimental data are compared with numerical Navier-Stokes solutions. The estimation of total uncertainty of the present measurements is about plus or minus 10 percent, which makes them suitable for CFD code validation purposes. The measured peak heat transfer data are correlated with the normal Mach number based on the concept of the quasi-conical nature of such interactions, and the results show good agreement with other experimental data.

THE RATE FORM OF EQUILIBRIUM EQUATION FOR PROBLEMS OF STEADY-STATE, ELASTIC, VISCOUS FLOWS Ph.D. Thesis
Lung John Tsai 1992 82 p
Avail: Univ. Microfilms Order No. DA9303900

The development of a numerical simulation for steady-state, elastic, viscous flows in two dimensions is presented. A mixed finite element method is used to couple the rate-equilibrium and the rate-constitutive equations by using successive substitution to solve for the velocity field and the stress field simultaneously. The method is applied to the flow analysis of co-rotational Maxwell (CRM), upper convective Maxwell (UCM), and four-element UCM fluid models. A flow through contraction problem is analyzed for the CRM, UCM and four-element UCM models. For both the CRM and UCM modles, the purely elastic case is compared to a solution found by using a linear formulation and it is found to compare favorably. For the purely viscous case, comparison is made with results obtained using the mixed formulation for velocity and pressure. Again, the results compare quite favorably. For the four-element UCM model, it is compared with the conventional UCM model. For the purely elastic and the purely viscous cases both models compare very well, and two examples are given for simulating both the Oldroyd-B and the Kelvin-Voigt models. From this illustration, the four-element UCM model is shown to work well for a wide range of constitutive behaviors. A second example presents an analysis of a metal forming rolling problem in the presence of free surfaces. For the purely elastic case, a decent solution of the velocity and stress distributions in the control volume for both CRM and UCM fluids is found. However, when the viscous effect is increased in the material, the free surface exhibits a continual swelling on the downstream side and the accuracy of the stress distribution deteriorates. In spite of the progress made on the free surface problem, the solutions for free surface problem presented in this dissertation are not yet of sufficient accuracy to be directly applicable to practical forming process design or analysis. The final example is an application of the rate-equilibrium formulation for elastic, nonlinear-viscous flows. It is shown that the method converges to reasonable solutions and hence the procedure has possible applications to metal forming processes. Dissert. Abstr.

FLOW AND HEAT TRANSFER EXPERIMENTS IN THE TURBINE AIRFOIL/ENDWALL REGION Ph.D. Thesis
Jin Taek Chung 1992 277 p
Avail: Univ. Microfilms Order No. DA9236936

An experimental investigation of the three-dimensional flow and heat transfer near the junction between the endwall and suction wall of a gas turbine was performed. A large-scale, two-half-blade facility which simulates a turbine cascade was introduced. The simulator consists of two large half-blade sections, one wall simulating the pressure surface and the other wall simulating the suction surface. The advantage of this configuration is

that the features of the secondary flow are large, because of the relatively large test section, and the flow is easily accessible with probes. Qualification of this simulator was by comparison to a multi-blade cascade flow. Various flow visualization techniques--oil and lampblack, ink and oil of wintergeeen, a single tuft probe, and a tuft grid--were employed to confirm that the important features of the cascade flow were replicated in this simulator. The triangular region on the suction surface, which was affected by the passage vortex, and the endwall secondary crossflow were observed by shear stress visualization and the liquid crystal measurement techniques. In order to investigate the effects of the turbulence level on the secondary flow in a turbine passage, a turbulence generator, designed to reproduce the characteristics of a combustor exit flow, was built. The generator was designed not only to generate a high turbulence level but to produce three main features of a combustor exit flow. The generator produced a turbulence intensity level of about 10 percent and an integral length scale of 5 centimeters. It was observed that the endwall secondary flow, including the passage vortex, is not significantly influenced by freestream turbulence levels up to 10 percent. A flow management technique using a boundary layer fence designed to reduce some harmful effects of secondary flow in the endwall region of a turbine passage was introduced. The boundary layer fence is effective in changing the passage of the vortex and reducing the influence of the vortex near the suction wall. The fence was even more effective in reducing secondary flows for high levels of freestream turbulence (approximately 10 percent). Dissert. Abstr.

TWO-DIMENSIONAL FIN ANALYSIS Ph.D. Thesis
Hyung Suk Kang 1992 110 p
Avail: Univ. Microfilms Order No. DA9224672

This dissertation deals with the variation of heat loss from the fin and the temperature distribution within the fin using a two-dimensional analysis for rectangular and triangular fins. For the rectangular fins, the root temperature is assumed to vary as cosine function across the fin root and the surface convection coefficients of the fin are assumed to be constant but unequal. The analysis is restricted to Biot numbers (= hl/k) such that 0 is less than or equal to B2 is less than or equal to B1 is less than or equal to 1, and B1 = 1, 0.1, 0.01, where B1 is the Biot number of the top surface and B2 is the Biot number of the bottom surface. For the triangular fins, the root temperature and surface convection coefficient are assumed to be constant. A comparison of the two dimensional temperature distribution within the fin and heat transfer rate from the fine, computed using a non-traditional (forced) analytic method and finite difference method, is made. Finally a one-dimensional analyses of the triangular fin is made using a statistical method. The results of these analyses will be helpful when the actual experimental set up is built and used in the laboratory. For the rectangular fins, the results show that the value of the tip Biot number is not important in the heat loss predictions when B1 and B2 are large. Under certain circumstances, the heat loss from the fin is essentially independent of the ratio of the fin length to the fin half width. For the triangular fins, the results show that when the Biot number is less than 0.1 (i.e., under usual circumstances), the forced analytic method is applicable. The statistical method yields a reasonably accurate value of the convection coefficient, h, using actual experimental data. Dissert. Abstr.

PARTICLE DYNAMICS MODELING OF BOUNDARY EFFECTS IN GRANULAR COUETTE FLOW Ph.D. Thesis
Hyeong-Jin Kim 1992 299 p
Avail: Univ. Microfilms Order No. DA9235729

This study provides insights in understanding boundary effects on the flow of dry granular materials composed of identical, smooth, inelastic spheres between parallel, bumpy walls in the absence of gravity. The results of this study are useful in providing a basis upon which developing theories can be modified as well as substantiating previous and current experiments. This in turn has a major importance in many industries which are concerned with handling of particulates, such as coal, mineral processing, powder metallurgy, and agriculture. The particle dynamics or discrete element method is used to model this flow, thereby providing a means of obtaining macroscopic information from the detailed particle-level multi-body dynamics. A shearing flow is induced by allowing the upper and lower walls to move with the same constant velocity in opposite directions. The wall geometry is characterized by several parameters - the spacing between the wall half-spheres and their geometric arrangement, diameter ratio of the wall to flow spheres, shear gap height and particle inelasticity measured by a constant normal restitution coefficient. Boundary roughness is either increased or decreased by appropriately adjusting the spacing between wall half-spheres or by changing the diameter ratio. For 'small' systems, a large stress drop occurs for dense flows when the wall particles are tightly packed. In this case, a layered shearing flow is present. However, as the shear gap height is increased while maintaining the same wall conditions, the stress drop does not occur. Computed wall stress components and slip velocities are very sensitive to boundary parameters. The ratio of shear to normal wall stresses is found to be independent of shear gap heights for fixed wall conditions. As wall roughness increases or flow particles become more elastic, slip velocity decreases thereby reducing the effectiveness of the walls in supplying momentum to the flow. A pronounced reduction in slip velocity is observed with increasing wall roughness for relatively elastic particles. Dissert. Abstr.

AN EXPERIMENTAL STUDY OF PASSIVE DRAG REDUCTION IN A TURBULENT BOUNDARY LAYER BY A RIBLET SURFACE Ph.D. Thesis
Seong-Ryong Park 1992 232 p
Avail: Univ. Microfilms Order No. DA9304378

An experimental study was performed with a single-sensor hot-wire probe in the wall region of a nominally zero pressure gradient turbulent boundary layer over smooth and V-groove riblet plates of h(+) approximately 14, s(+) approximately 28 at Re(sub theta) is approximately equal to 1200. The shear stress variation in the span wise direction and the alteration of the turbulent characteristics were directly measured. The span wise average shear stress on riblet groove was obtained and contour lines were fitted to the measurement for all the statistics. Net drag reduction of about 4 percent was found for this case, in substantial agreement with previous direct measurement. The synthetic analysis, at y(+) approximately 30, of a modified Kovasznay-type probe was performed and an improvement algorithm was developed. The performance of a cross-shaped four-sensor probe in the turbulent boundary layer in the highly sheared region (y+ approximately 4) is also presented. To further understand the flow structure inside the riblet, four-sensor hot wire probes of a modified version of the original Kovaszny-type and of a cross-shaped were used over the two test surfaces at Re is approximately equal to 2500 and 2100, respectively. Statistical properties of the fluctuating velocity components and the Reynolds stress, including joint probability density functions and frequency spectra of data obtained over the smooth and the peak and over the valley of the riblet plate are presented. Dissert. Abstr.

FLOW BETWEEN FINITE ROTATING DISKS AND ITS LINEAR STABILITY Ph.D. Thesis
Dong Fu 1992 184 p
Avail: Univ. Microfilms Order No. DA9236113

The flow between finite rotating disks with a large aspect ratio (beta = R/d, where d is the gap between the disks and R is the radius of the disk) and its linear stability are studied. Through an analysis of the singular points of the governing equations, some quasi-similar properties of basic flow with respect to certain parameters are obtained. Extensive numerical experiments on the basic flows are conducted by projecting governing equations onto a polynomial subspace with a B-spline basis. The numerical results have very good agreement with the experimental data of Szeri and strongly support the theoretical predictions. The linear stability of the basic flow, with beta(sup 2) = 406.5 and beta(sup 2) = 1975.3, is studied in detail. The perturbation equations which characterize the stability of the finite disk flow are derived and solved numerically. Three types of unstable modes are found. These are: (1) S(sub W), introduced by and located near the side wall; (2) S(sub L), consisting of spiral-like vortices, which occurs at mid radius; and (3) S(sub R), appearing when the Reynolds number of the basic flow is large. The numerical predictions for critical Reynolds number are in good agreement with the experimental data of Sirivat. Dissert. Abstr.

LARGE-EDDY SIMULATION OF TEMPORALLY DEVELOPING BOUNDARY LAYERS WITH EMBEDDED STREAMWISE VORTICES

Ph.D. Thesis
Hossein Esmaili 1992 147 p
Avail: Univ. Microfilms Order No. DA9234560

The interaction of streamwise vortices with turbulent boundary layer has been investigated using large-eddy simulation. The embedded vortices are a pair of counter-rotating Oseen vortices with flow between them directed towards the wall (common-flow-down), superimposed on various instantaneous realizations of flat plate and sink flow turbulent boundary layers. The time development of the vortices and their interaction with the boundary layer are studied by integrating the filtered Navier-Stokes equations in time. The most important effects of the vortices on the boundary layer are the thinning of the boundary layer in the downwash region between the vortices and its thickening in the upwash region. The Reynolds stress profiles highlight the highly three-dimensional structure of the turbulent boundary layer modified by the vortices. The presence of significant turbulent activity near the vortex center and in the upwash region where inflectional velocity profiles are observed, suggests that localized instability mechanisms in addition to the convection of turbulent energy by the secondary flow are responsible for this effect. High levels of secondary stresses in the vicinity of the vortex center are also observed. These simulations also indicate that eddy viscosity models should be expected to perform poorly in the vortex core region. The numerical results for the flat plate turbulent boundary layer show good agreement with the experimental results of Pauley and Eaton (1988a,b). The mean features of flow show the same patterns for both the flat plate and sink flow turbulent boundary layers.

THERMOCAPILLARY FLOW NEAR A COLD WALL Technical Report, Jan. - Dec. 1992
David Canright 20 Jan. 1993 43 p
(AD-A261050; NPS-MA-93-011) Avail: CASI HC A03/MF A01

The following model problem examines the thermocapillary feedback mechanism important at the edge of weld pools and other materials processes. A pool of liquid with a flat horizontal free surface is bounded on one side by a vertical solid wall, which is maintained at a cold temperature to unit depth, and at a warmer temperature below; far away the fluid is at the warmer temperature. Surface tension is a decreasing function of temperature, so that the surface thermal gradient drives flow toward the corner. When convection is vigorous, the flow compresses the thermal gradient which is driving the flow; this positive feedback results in small local length scales and high velocities near the corner. This problem is examined through a detailed scaling analysis and through numerical simulation for a range of parameters.

CORRELATIONS BETWEEN ORGANIZED TURBULENT STRUCTURES AND WALL PRESSURE FLUCTUATIONS
Vincent Wilczynski and Mario J. Casarella (Catholic Univ. of America, Washington, DC.) Sep. 1992 19 p
(PB93-156479; USCGA-TR-11-92) Avail: CASI HC A03/MF A01

The investigation examines the relationship between flow structures observed across the boundary layer and their wall pressure signatures. Experimental data of simultaneous wall pressure and velocity fluctuations have been obtained in a low noise flow facility and analyzed using statistical and spectral methods. First, the individual properties were examined to observe their unique features in the inner and outer regions. Next, the joint probability and cross-spectra between stream wise and wall-normal velocity fluctuations were investigated to study distinctive features of both the Reynolds stress within the boundary layer, and the observed irrotational motion at the edge of the boundary layer. Finally, to evaluate a proposed correlation between the spatial locations of turbulent sources and the frequency bands of the wall pressure spectrum, cross-spectral data between the wall pressure spectrum and velocity fluctuations are examined. The distinct contributions to the wall pressure spectrum from the band-limited irrotational motion, and regions of high turbulent production are identified.

UNIFORM ROUGHNESS STUDIES Final Report, Sep. 1987 - Mar. 1992
D. E. Klett and M. Kithcart May 1992 82 p
(Contract F33615-C-87-3022)
(WL-TR-92-3041) Avail: CASI HC A05/MF A01

Heat transfer, skin friction, turbulence intensity, and velocity profile data were obtained for 22 different rough surfaces in turbulent subsonic boundary layer air flow. The rough surfaces consisted of hemispherical dimples, hemispherical protrusions, and rectangular protrusions. The rectangular roughness plates were tested with the tops of the elements flush with the upstream smooth surface and with the tops protruding above the smooth surface. The surfaces with protrusions were designed to have values of the Simpson roughness shape/spacing parameter that bracket the peak in the equivalent sand-grain correlation. The data was used for comparison with predictions from a discrete element rough surface boundary layer code in an attempt to improve the code's performance for cases of closely spaced roughness elements when wakes behind individual elements overlap. An anomaly was discovered in the code that causes wide variations in predicted drag and heat transfer for small variations in element drag coefficient C(sub d). The problem lies in the effect of C(sub d) on the velocity calculation giving rise to inflections in the calculated velocity profile near the crests of the roughness elements. A remedy to the problem has not, as yet, been found.

NUMERICAL SIMULATION OF PERMEATION FROM DEPOSITED DROPLETS: MODEL EXPANSION Final Report
Geralda Severe and Jerry H. Meldon Apr. 1992 69 p
(DA Proj. 1L1-62105-AH-84)
(MTL-TR-92-23) Avail: CASI HC A04/MF A01

A previously published model of permeation from a droplet has been expanded. The effects of downstream mass transfer resistance and concentration dependence of the diffusion coefficient are included. An attempt was made to fit experimental results for the permeation of di-iso-propyl- methyl-phosphonate (DIMP) through Neoprene and natural rubber. Simulated data do not reproduce the initial pronounced delay of experimental permeation. Furthermore, no rationale was identified for the anomalous dependence of 'breakthrough time' upon barrier thickness observed with several experimental systems.

DSD TECHNOLOGY: A DETONATION REACTIVE HUYGENS CODE
John Bdzil and Wildon Fickett Jul. 1992 52 p
(LA-12235-MS; UC-741; UC-705) Avail: CASI HC A04/MF A01

The length of the reaction zone strongly influences the speed of propagation of detonation in multi-dimensional explosive pieces. Detonation Shock Dynamics (DSD) properly accounts for these effects in detonation wave-spreading problems when the radius of curvature of the multi-dimensional detonation shock is large compared to the explosive's reaction-zone length. This report is a user manual for our two-dimensional implementation of this method, a FORTRAN subroutine called DSD Technology.

The invention is a method for measuring the wavelength of cross-flow vortices of air flow having streamlines of flow traveling across a swept airfoil. The method comprises providing a plurality of hot-film sensors. Each hot-film sensor provides a signal which can be processed, and each hot-film sensor is spaced in a straight-line array such that the distance between successive hot-film sensors is less than the wavelength of the cross-flow vortices being measured. The method further comprises determining the direction of travel of the streamlines across the airfoil and positioning the straight-line array of hot film sensors perpendicular to the

direction of travel of the streamlines, such that each sensor has a spanwise location. The method further comprises processing the signals provided by the sensors to provide root-mean-square values for each signal, plotting each root-mean-square value as a function of its spanwise location, and determining the wavelength of the cross-flow vortices by noting the distance between two maxima or two minima of root-mean-square values.

(AD-A261599; GALCIT-FM92-1; AFOSR-93-0133TR) Avail: CASI HC A03/MF A01

This paper focuses on the correlation of two successive scalar images for the purpose of measuring imaged fluid motions. A method is presented for deforming, or transforming, one image to another. Taylor series expansions of the Lagrangian displacement field are used, in conjunction with an integral form of the equations of motion, to approximate this transformation. The proposed method locally correlates images for displacements, rotations, deformations, and higher order displacement gradient fields and applies a global minimization procedure to insure a global consistency in the results. An integral form of the equations of motion is employed and, as a consequence, no spatial or temporal differentiation of the image data is required in estimating the displacement field. Successive two-dimensional digital CCD images of fluid motion marked with dye are used to verify the capabilities of the method. The utility of the method is also illustrated using a pair of Voyager 2 images of Jupiter.

MODEL FAN PASSAGE FLOW SIMULATION M.S. Thesis
David D. Myre Dec. 1992 172 p
(AD-A261613) Avail: CASI HC A08/MF A02

Two-dimensional experimental and numerical simulations of a transonic fan blade passage were conducted at a Mach number of 1.4 to provide baseline data for the study of the effects of vortex generating devices on the suction surface shock-boundary layer interaction. In the experimental program, a probe and traverse system were designed and constructed. A new data acquisition system was adapted to record data from probe measurements and multiple scans of static pressure ports. Impact pressure behind two model fan passages and static pressures across the shock-boundary layer interaction were measured for a design and one off-design flow incidence in a blow-down wind tunnel. The passage shocks were positioned in similar locations by rotating the model to a decreased flow incidence. Fan passage losses were obtained by integrating probe measurements. The losses compared favorably with a numerical Navier-Stokes solution and one engineering loss model, Static pressure distributions were also found to compare favorably with numerical results.

AN EXTENDED LAGRANGIAN METHOD
Meng-Sing Liou May 1992 28 p
(RTOP 505-62-52)
(NASA-TM-106129; E-7798; NAS 1.15:106129) Avail: CASI HC A03/MF A01

A unique formulation of describing fluid motion is presented. The method, referred to as 'extended Lagrangian method', is interesting from both theoretical and numerical points of view. The formulation offers accuracy in numerical solution by avoiding numerical diffusion resulting from mixing of fluxes in the Eulerian description. Meanwhile, it also avoids the inaccuracy incurred due to geometry and variable interpolations used by the previous Lagrangian methods. Unlike the Lagrangian method previously imposed which is valid only for supersonic flows, the present method is general and capable of treating subsonic flows as well as supersonic flows. The method proposed in this paper is robust and stable. It automatically adapts to flow features without resorting to clustering, thereby maintaining rather uniform grid spacing throughout and large time step. Moreover, the method is shown to resolve multi-dimensional discontinuities with a high level of accuracy, similar to that found in one-dimensional problems.

The effort has had several components since it was initiated in Oct of 1989; all of these had as their objective the assistance of Dr. Joseph Shang at WRDC in the redirection of his effort toward use of massively-parallel architectures. The major objective was to gain algorithm experience in conversion of two Air Force production CFD codes to a general format applicable to a variety of commercial message-passing architectures. Earlier, an explicit N-S 3D code from WRDC had been converted to the NCUBE. This was used as a model for parallelized production code developed at WRDC under DARPA sponsorship. This effort was completed with the conversion of a serial full 3D Navier-Stokes Beam-Warming CFD code to a 1024-node scalar NCUBE hypercube at SANDIA (Albuquerque).

Single-point, jet-fluid concentration measurements obtained from high Schmidt number (Sc approximately equal to 1.9 x 10(exp 3)) turbulent jets permit an investigation of temporal scalar power spectra, for jet Reynolds numbers in the range of 1.25 less than or equal to Re x 10(exp -4) less than or equal to 7.2. At intermediate scales, we find a spectrum with a logarithmic derivative (slope) that is increasing with Reynolds number, in absolute value, but less than 5/3 at the highest Reynolds number in our experiments. At the smallest scales, our spectra exhibit no 1-k power-law behavior, possessing a log-normal region over a range of scales exceeding a factor of 40, in some cases.

A review of the research that has been carried out under the sponsorship of Air Force Office of Scientific Research grant number AFOSR-90-0179 is given. Details are given about two research programs, namely flow control and superconductivity. In both instances we have modeled realistic physical problems, we have performed rigorous analysis on the mathematical models, we have developed approximation schemes which we have also analyzed, and we have written computer codes implementing our computational method. In both instances, were the first to carry out such a comprehensive research program, and in so doing, have developed robust and useful algorithms that also embarked on a joint research program with personnel at AEDC facility in Tullahoma, Tennessee. We also briefly discuss other accomplishments related to this grant, including other research project invited talks, journal articles, etc. DTIC

FLOW CONDITIONER LOCATION EFFECTS IN ORIFICE FLOWMETERS
J. L. Scott, C. F. Sindt, and M. A. Lewis Jan. 1993 72 p See also PB92-189521 and PB92-183730
(PB93-159457; NIST/TN-1356) Avail: CASI HC A04/MF A01; SOD HC

Tests sponsored by Gas Research Institute were conducted with orifice flowmeters of two nominal sizes: 104 mm and 52 mm. For the 104 mm orifice meter, the authors compared discharge coefficients measured in two common piping configurations used by laboratories to establish baseline flow conditions. The discharge coefficients are similar for beta ratios of 0.43, 0.55, and 0.67, but not for the 0.73 beta ratio plate. For other tests with the orifice meter, a 90 degree elbow or a reducer was located upstream of the orifice plate and flow conditioner. Two beta ratios (0.54, 0.67) were tested in the 52 mm orifice meter in baseline configuration and with an elbow at 17D and a flow conditioner at 12D. For many of the tests, differential pressures were measured at more than one flange tap location. Placing the flow conditioner too close to the orifice plate in either meter yields discharge coefficients below baseline values. The location of the flow conditioner with respect to the orifice plate appears to influence meter performance more significantly than the type or location of flow disturbance upstream of it. NTIS

ANOTHER LOOK AT THE DRIVEN CAVITY PROBLEM Final Report
Max A. Stafford 2 Nov. 1992 41 p
(AD-A261903; USAFA-TR-92-4) Avail: CASI HC A03/MF A01

Numerical analysis of a lid driven cavity is a standard computational fluid dynamics problem. A semi-discrete method known as the method of lines is used to reduce the problem to one of solving a coupled system of first-order linear differential equations and linear algebraic equations. The spectrum of the coefficient matrix in the first-order system of differential equations is analyzed as the flow field evolves from rest to steady state. By examining the pattern of this eigenvalue migration, it is possible to estimate the time to steady state by using very coarse grids. A simple relationship between the Reynolds number and time to steady state is also apparent from analyzing the coefficient matrix. DTIC

A fractional-step splitting scheme breaks the full Navier-Stokes equations into explicit and implicit portions amenable to the calculus of variations. Beginning with the functional forms of the Poisson and Helmholtz equations, we substitute finite expansion series for the dependent variables and derive the matrix equations for the unknown expansion coefficients. This method employs a new splitting scheme which differs from conventional three-step (nonlinear, pressure, viscous) schemes. The nonlinear step appears in the conventional, explicit manner, the difference occurs in the pressure step. Instead of solving for the pressure gradient using the nonlinear velocity, we add the viscous portion of the Navier-Stokes equation from the previous time step to the velocity before solving for the pressure gradient. By combining this 'predicted' pressure gradient with the nonlinear velocity in an explicit term, and the Crank-Nicholson method for the viscous terms, we develop a Helmholtz equation for the final velocity. To measure icing patterns across a test section of the Icing Research Tunnel, an automated rotating bar measurement system was developed at NASA LeRC. In comparison with the previously used manual measurement system, this system provides a number of improvements: increased accuracy and repeatability, increased number of data points, reduced tunnel operating time, and improved documentation. The automated system uses a linear variable differential transformer (LVDT) to measure ice accretion. This instrument is driven along the bar by means of an intelligent stepper motor which also controls data recording. This paper describes the rotating bar calibration measurement system. MEASUREMENTS OF DENSITY, TEMPERATURE, AND THEIR FLUCTUATIONS IN TURBULENT SUPERSONIC FLOW USING UV LASER SPECTROSCOPY
Douglas G. Fletcher and R. L. McKenzie Oct. 1992 9 p Presented at the 6th International Symposium on Applications of Laser Techniques to Fluid Mechanics, Lisbon, Portugal, 20-23 Jul. 1992
(RTOP 505-59-00)
(NASA-TM-103943; A-92120; NAS 1.15:103943) Avail: CASI HC A02/MF A01

Nonintrusive measurements of density, temperature, and their turbulent fluctuation levels were obtained in the boundary layer of an unseeded, Mach 2 wind tunnel flow. The spectroscopic technique that was used to make the measurements is based on the combination of laser-induced oxygen fluorescence and Raman scattering by oxygen and nitrogen from the same laser pulse. Results from this demonstration experiment are compared with previous measurements obtained in the same facility using conventional probes and an earlier spectroscopic technique. Densities and temperatures measured with the current technique agree with the previous surveys to within 3 percent and 2 percent, respectively. The fluctuation

amplitudes for both variables agree with the measurements obtained using the earlier spectroscopic technique and show evidence of an unsteady, weak shock wave that perturbs the boundary layer. Author (revised)

DEVELOPMENT OF THIN FILM THERMOCOUPLES ON CERAMIC MATERIALS FOR ADVANCED PROPULSION SYSTEM APPLICATIONS

Raymond Holanda Feb. 1993 16 p Presented at the Conference for Preparation for Temperature: Its Measurement and Control in Science and Industry, Toronto, Ontario, 28 Apr. - 2 May 1992; sponsored by AIP, ISA, NIST, and NRC

(RTOP 510-01-50)

(NASA-TM-106017; E-7574; NAS 1.15:106017) Avail: CASI HC A03/MF A01

Thin film thermocouples were developed for use on metal parts in jet engines to 1000 C. However, advanced propulsion systems are being developed that will use ceramic materials and reach higher temperatures. The purpose is to develop thin film thermocouples for use on ceramic materials. The new thin film thermocouples are Pt13Rh/Pt fabricated by the sputtering process. Lead wires are attached using the parallel-gap welding process. The ceramic materials tested are silicon nitride, silicon carbide, aluminum oxide, and mullite. Both steady state and thermal cycling furnace tests were performed in the temperature range to 1500 C. High-heating-rate tests were performed in an arc lamp heat-flux-calibration facility. The fabrication of the thin film thermocouples is described. The thin film thermocouple output was compared to a reference wire thermocouple. Drift of the thin film thermocouples was determined, and causes of drift are discussed. The results of high heating rate tests up to 2500 C/sec are presented. The stability of the ceramic materials is examined. It is concluded that Pt13Rh/Pt thin film thermocouples are capable of meeting lifetime goals of 50 hr or more up to temperatures of 1500 C depending on the stability of the particular ceramic substrate.

ATOMIZING-GAS TEMPERATURE EFFECT ON CRYOGENIC SPRAY DROPSIZE

Robert D. Ingebo Jun. 1993 12 p Prepared for presentation at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE

(RTOP 505-62-52)

(NASA-TM-106106; E-7754; NAS 1.15:106106) Avail: CASI HC A03/MF A01

Correlating expressions for two-phase flow breakup of liquid nitrogen, LN2, jets in sonic velocity nitrogen gasflows were obtained for an atomizing-gas temperature range of 111 to 442 K. The correlations were based on characteristic dropsize measurements obtained with a scattered-light scanner. The effect of droplet vaporization on the measurements of the volume-median dropsize was calculated by using previously determined heat and momentum transfer expressions for droplets evaporating in high-velocity gasflow. Finally, the dropsize of the originally unvaporized spray was calculated, normalized with respect to jet diameter and correlated with atomizing-gas flowrate and temperature. Author

AN ACTIVE SOLID STATE RING LASER GYROSCOPE Ph.D. Thesis

Timothy Joseph Valle 1992 174 p

Avail: Univ. Microfilms Order No. DA9304610

The properties of an active, solid state ring laser gyroscope were investigated. Two laser diode pumped monolithic nonplanar ring oscillators (NPRO), forced to lase in opposite directions, formed the NPRO-Gyro. It was unique in being an active ring laser gyroscope with a homogeneously broadened gain medium. This work examined sources of technical and fundamental noise. Associated calculations accounted for aspects of the NPRO-Gyro performance, suggested design improvements, and outlined limitations. The work brought out the need to stabilize the NPRO environment in order to achieve performance goals. Two Nd:YAG NPRO's were mounted within an environment short term stabilized to microdegrees Celsius. The Allan variance of the NPRO-Gyro beat note was 500 Hz for a one second time delay. Unequal treatment of the NPRO's appeared as noise on the beat frequency, therefore reducing its rotation sensitivity. The sensitivity to rotation was limited by technical noise sources. Dissert. Abstr.

NOVEL APPROACHES TO THE CONSTRUCTION OF MINIATURIZED ANALYTICAL INSTRUMENTATION

Marc D. Porter, Ronald P. OToole, Shelley J. Coldiron, William D. Deninger, Randall S. Deinhammer, Stanley G. Burns, Glenn J. Bastiaans, Steve D. Braymen, and Howard R. Shanks [1992] 20 p

(Grant NAG2-722)

(NASA-CR-191988; NAS 1.26:191988) Avail: CASI HC A03/MF A01

This paper focuses on the design, construction, preliminary testing, and potential applications of three forms of miniaturized analytical instrumentation. The first is an optical fiber instrument for monitoring pH and other cations in aqueous solutions. The instrument couples chemically selective indicators that were immobilized at porous polymeric films with a hardware package that provides the excitation light source, required optical components, and detection and data processing hardware. The second is a new form of a piezoelectric mass sensor. The sensor was fabricated by the deposition of a thin (5.5 micron) film of piezoelectric aluminum nitride (AlN). The completed deposition process yields a thin film resonator (TFR) that is shaped as a 400 micron square and supports a standing bulk acoustic wave in a longitudinal mode at frequencies of approx. 1 GHz. Various deposition and vapor sorption studies indicate that the mass sensitivity of the TFR's rival those of the most sensitive mass sensors currently available, though offering such performance in a markedly smaller device. The third couples a novel form of liquid chromatography with microlithographic miniaturization techniques. The status of the miniaturization effort, the goal of which is to achieve chip-scale separations, is briefly discussed. Author (revised)

HIGH SPEED X RAY GATING CAMERAS FOR ICF IMAGING APPLICATIONS

P. M. Bell, J. D. Kilkenny, O. Landen, D. B. Ress, J. D. Wiedwald, D. K. Bradley (Rochester Univ., NY.), J. Oertel, and R. Watt (Los Alamos National Lab., NM.) Dec. 1992 22 p Presented at the 20th International Congress on High Speed Photography and Photonics, Victoria, Ontario, 25-26 Sep. 1992

(Contract W-7405-eng-48)

(DE93-007500; UCRL-JC-112256; CONF-9209188-8) Avail: CASI HC A03/MF A01

High speed, high x-ray energy imaging of implosions is a key diagnostic technique in the glass laser implosion program in the USA. With the correct x-ray energy, time gated images can measure the symmetry and mix of the imploding shell into the stagnated fuel if the spatial resolution of 10 or 5 microns is matched by a temporal resolution of 100 or 50 psec. Several 100 psec microchannelplate (MCP) x-ray pin hole cameras were installed and run on large laser systems with improving reliability. To increase the sensitivity of the imaging system, a ring aperture microscope was coupled to a gated MCP detector allowing imaging at up to 8 keV. To achieve 40 psec resolution, thinner MCP's are required. On line tests with a thin low gain, but high speed MCP, followed by a d.c. MCP for higher gain have demonstrated 40 psec gating, but the second plate may lead to an unacceptable sensitivity of the camera to hard x-rays. Off line tests have extensively investigated the properties of thinner MCP's and good agreement is seen with modeling. DOE

A HIGH PERFORMANCE ROOM-TEMPERATURE NEAR-INFRARED CAMERA Final Report, 1 Jul. - 31 Dec. 1992

Marshall J. Cohen, Gregory H. Olsen, and Robert Trew 20 Jan. 1993 22 p

(Contract DAAL03-92-C-0040)

(AD-A260602; ARO-30479.1-EL-SBI) Avail: CASI HC A03/MF A01

The objective of this program is to advance InGaAs materials technology to allow high performance imaging at room temperature in the 1.0-2.6 micron near infrared band. During Phase I, 128x128 pixel lattice-matched In(.53)Ga(.47)As focal plane arrays from 1-1.7 micron were fabricated. The detectivity, D*, was 10(exp 13) cm-Hz(exp .5)/W at room temperature and greater than 3x10(exp 14) at 230K - a value very nearly background

limited. The standard deviation in D* was 14 percent of the mean value and 98 percent of the pixels has a D* greater than 50 percent of the mean value. These results significantly advance the state-of-the-art and all of the objectives of Phase I were met or exceeded. The goals of Phase II will be to advance the materials growth and processing technologies of lattice mismatched InGaAs so as to lower the dark current sufficiently that room temperature imaging in the 1.0-2.6 micron band can be performed. This goal has proven elusive despite investments of tens of millions of dollars over more than a decade. Potential applications of this research include remote atmospheric sensing, LIDAR, satellite imaging, and near infrared spectroscopy. DTIC

(Contract DAAL03-90-C-0029)
(AD-A260747; ARO-28148.2-EL-SB2) Avail: CASI HC A03/MF A01

The following document details the results of efforts to develop a high temperature sensor technology based in Kopin's proprietary ISE SOI material. Results are presented from a detailed analysis of the piezoresistive properties, and of the internal stress in the layer. These results show the material to be electrically similar to bulk, with very low internal stress. This makes ISE(tm) an ideal material choice for this application. A full sensor process sequence, with mask set, and enabling process equipment and techniques, was developed for this program. In parallel with the process development, extensive circuit analysis and modeling was performed to identify the best high temperature sensing circuit for this task. After modeling, test circuits were fabricated in bulk wafers to evaluate the design. The final design, a switching capacitive MOS circuit with proportional output, is expected to produce a sensor with 0.1 percent accuracy over the temperature range of -60 C to 300 C. Kopin is currently pursuing industrial financing for Phase 3 of this work to complete the integration of this work for commercial application. DTIC

INTRODUCTION TO LEAD SALT INFRARED DETECTORS Technical Report, Sep. 1990 - Sep. 1992
David A. Kondas Feb. 1993 26 p
(AD-A260781; ARFSD-TR-92024) Avail: CASI HC A03/MF A01

This technical report establishes the background necessary to understand how lead sulfide (PbS) and lead selenide (PbSe) infrared detectors operate. Both detectors, which are members of the lead salt family of infrared detectors, use the photoconductive effect to detect energy residing within the infrared region of the electromagnetic spectrum. PbS detectors are useful for detecting energies in the 1 to 3 micrometer region, while PbSe detectors can detect energies in the 1 to 7 micrometer region. They are essentially polycrystalline thin films which are fabricated by chemical deposition techniques in either single element or multi-element array configurations. The significance of the electronic structure of these crystalline films and the effects of temperature on their operation and performance are discussed. The history of the development of lead salt detectors from the early years before World War I to the more recent developments is detailed. In addition, an overview of a typical infrared system is also presented. DTIC

HIGH LEVEL DESIGN FOR DISTRIBUTED APPLICATION INSTRUMENTATION
Vaughn T. Combs and Cheryl L. Blake Sep. 1992 55 p
(AF Proj. 5581)
(AD-A260812; RL-TR-92-181) Avail: CASI HC A04/MF A01

This paper describes the high level design for a distributed application instrumentation package. The instrumentation package provides monitoring tools to aid application designers in developing and understanding the behavior of their applications within an object-oriented distributed environment. The package consists of a general query-based system for the collection of events that occur within an application and a display system for processing and presenting the events. These events are collected through the use of probes which register events with a distributed database. Calls to these probes are embedded within the code to be instrumented in order to mark the occurrence of a specific event. The instrumentation package will provide a library of predefined probes based on events that adhere to the object/thread model (e.g. thread entrances into objects, thread exits from objects, etc.) and will also allow for user-defined probes. The display to be provided will represent object/thread interactions. The design is built flexibly so as to permit a wide range of events and displays to be used with the package. DTIC

US-Patent-Class-364-453) Avail: US Patent and Trademark Office

A method of automatically determining attitude of a moving vehicle is described. Acceleration of the moving vehicle is measured with gyro stabilized accelerometers. The measurement is converted to a motion related vector in a first frame of reference. The coordinates are read into a computer. The cosine value and the sine value for an Euler rotation of the first frame of reference are read into the computer. The computer produces coordinates of the vector in a rotated frame of reference. The above two steps are repeated a number of times to arrive at a final frame of reference. The attitude of the vehicle is provided with respect to a final frame of reference with the aid of final produced coordinates. DTIC

MAGNETIC MULTILAYER STRAIN GAGE Patent
Marilyn Wun-Fogle, inventor (to Navy), Arthur E. Clark, inventor (to Navy), and Kristl B. Hathaway, inventor (to Navy) 8 Dec. 1992 4 p Filed 1 Nov. 1991
(AD-D015672; US-Patent-5,168,760; US-Patent-Appl-SN-786641;
US-Patent-Class-73-779) Avail: US Patent and Trademark Office

A strain gauge is discussed. The gauge is comprised of a magnetic multilayer assembly exhibiting spin-valve effect with individual ferromagnetic

layers possessing magnetostrictive properties. A magnetic field source is used to bias the magnetic moments of the ferromagnetic layers in a given direction whereby stress applied causes previously antiferromagnetically coupled moments to be angularly realigned toward a ferromagnetic arrangement. Such realignment causes a corresponding resistance change of unexpectedly high magnitude thereby providing a highly sensitive strain gauge. DTIC

ADVANCED TECHNOLOGY DEVELOPMENT MULTI-COLOR HOLOGRAPHY Final Report, 24 Mar. 1992 - 24 Jan. 1993
Chandra S. Vikram 15 Jan. 1993 39 p
(Contract NAS8-38609)
(NASA-CR-192451; NAS 1.26:192451; UAH-5-32892) Avail: CASI HC A03/MF A01

This is the final report of the Multi-color Holography project. The comprehensive study considers some strategic aspects of multi-color holography. First, various methods of available techniques for accurate fringe counting are reviewed. These are heterodyne interferometry, quasi-heterodyne interferometry, and phase-shifting interferometry. Phase-shifting interferometry was found to be the most suitable for multi-color holography. Details of experimentation with a sugar solution are also reported where better than 1/200 of a fringe order measurement capability was established. Rotating plate glass phase shifter was used for the experimentation. The report then describes the possible role of using more than two wavelengths with special reference-to-object beam intensity ratio needs in multicolor holography. Some specific two- and three-color cases are also described in detail. Then some new analysis methods of the reconstructed wavefront are considered. These are deflectometry, speckle metrology, confocal optical signal processing, and phase shifting technique related applications. Finally, design aspects of an experimental breadboard are presented. The amplifier and beam shaping section of a new pulse generation system that will drive the Beamlet laser at Lawrence Livermore National Laboratory (LLNL) is described. The master oscillator and pulse shaping system are described in an accompanying contribution. A modified regenerative amplifier produces a gain of 10(exp 9) to bring the oscillator pulses to the mJ-level. A serrated aperture and birefringent beam shaper produce a flat-topped square beam with high fill factor. A single four-passed Nd:glass rod amplifier provides sufficient gain to generate the desired 12 J output energy in a 3 nsec pulse with very small beam profile, wavefront, and pulse shape distortion. A description of the system components is

presented followed by a discussion of its performance, based upon over 150 full front end shots being completed since its assembly. DOE

SURFACE DISCHARGE PHOTOINITIATION OF PULSED CHEMICAL LASERS
20 Oct. 1992 92 p Prepared in cooperation with Schafer (W.J.) Associates, Inc., Chelmsford, MA
(Contract W-7405-eng-36)
(DE93-006337; LA-SUB-93-13; WJSA-R-92-B-012) Avail: CASI HC A05/MF A01

This report summarizes the work carried out under the contract entitled Surface Discharge (SD) Photoinitiation Pulsed Chemical Lasers. This work consisted of technical analyzes, memos, and on-site test support. We considered SD design issues for both pulsed chemical lasers and photodissociation iodine lasers. Due to the similarity in the absorption band, the requirements on the SD light source are very similar. The SD systems can be utilized for either type of laser. Both rectangular and cylindrical SD configurations were analyzed. The cylindrical configuration is simpler, provides direct ultraviolet coupling into the laser medium, is smaller and lighter, and is better for voltage stand-off in multiple module configurations. But the impedance matching between the electrical circuit and the SD plasma is more difficult with the cylindrical geometry, unless small diameter cavities can be employed. A cylindrical configuration is preferred if the laser energy density is high enough for the diameter to be less than about 10 cm. A single rectangular SD module was tested for the first time at high voltage and worked very well. The four module system was integrated into the laser and SD tests conducted. Laser operation both in the DF-CO2 mode at 10.6 microns and the DF mode at about 3.8 microns were investigated. This is the first time an SD has been used in this configuration to produce laser energy outputs at the levels achieved. A weight scaling analysis of the pulsed power system was undertaken to support the application of this laser system. The pulsed power system will weigh 50 to 100 lbs, and provide 10 to 100 shots at repetition rates of less then 1 Hz. We concluded that the most practical approach to producing efficient ultraviolet emission from the SD at the short pulses needed for photoinitiation, and on the SD areas needed for the laser operation, employs a single capacitor bank rather than a pulser-sustainer approach. LASER DESORPTION IN AN ION TRAP MASS SPECTROMETER
G. C. Eiden, M. E. Cisper, M. L. Alexander, P. H. Hemberger, and N. S. Nogar 1993 12 p Presented at the International Society for Optical Engineering Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract W-7405-eng-36)
(DE93-007330; LA-UR-93-370; CONF-930159-9) Avail: CASI HC A03/MF A01

Laser desorption in a ion-trap mass spectrometer shows significant promise for both qualitative and trace analysis. Several aspects of this methodology are discussed in this work. We previously demonstrated the generation of both negative and positive ions by laser desorption directly within a quadrupole ion trap. In the present work, we explore various combinations of d.c., r.f., and time-varying fields in order to optimize laser generated signals. In addition, we report on the application of this method to analyze samples containing compounds such as amines, metal complexes, carbon clusters, and polynuclear aromatic hydrocarbons. In some cases, the ability to rapidly switch between positive and negative ion modes provides sufficient specificity to distinguish different compounds of a mixture with a single stage of mass spectrometry. In other experiments, we combined intensity variation studies with tandem mass spectrometry experiments and positive and negative ion detection to further enhance specificity. DOE

PARTICLE SIMULATION FOR 10.6 MICRON PICOSECOND LASER-INDUCED BREAKDOWN IN GASES Ph.D. Thesis
Quan Zhang 1992 109 p
Avail: Univ. Microfilms Order No. DA9233601

A theoretical model was developed to explain experimental observations in free electron laser experiments. Argon plasmas were initiated and sustained by a free electron laser operating at a wavelength of 10.6 microns with a sequence of 10 ps pulses, and attempts to obtain optical breakdown with the same laser in nitrogen and hydrogen proved unsuccessful. The particle simulation method was used in this model to calculate the electron density increase and the electron energy distribution during the gas breakdown process. A Monte Carlo collision method was incorporated into the particle simulation method to calculate collisions between particles. The theoretical model also included three-body recombination and gasdynamic expansion effects. The calculated results showed that the argon plasma breakdown in the free electron laser experiments was the result of a cumulative growth of the electron density during 27 pulses. Hydrogen and nitrogen did not reach breakdown at the free electron laser experiment conditions because the electron energy decayed more rapidly in these gases during the interval between pulses. The reduction of electron energy permits a much faster electron recombination rate which depletes the electron density during the interval between pulses. The particle simulation predicts that hydrogen and nitrogen can reach breakdown at a power threshold which is higher than that which was used in the free electron laser experiments. Author (revised)

ELECTRON-BEAM-PUMPED RECOMBINATION LASERS Ph.D. Thesis
Robert Lewis Rhoades 1992 81 p
Avail: Univ. Microfilms Order No. DA9236577

The first known instance of electron-beam pumping of the 546.1 nm mercury laser is reported. This has been achieved using high-energy electrons to create intense ionization in a coaxial diode chamber containing a mixture of noble gases with a small amount of mercury vapor. Also, the results of a study of the 585.3 nm neon laser in He:Ne:Ar mixtures under similar experimental conditions are reported. Both of these lasers are believed to be predominantly pumped by recombination. For the mercury laser, kinetic processes in the partially ionized plasma following the excitation pulse of high-energy electrons should favor the production of atomic mercury ions and molecular ions containing mercury. Subsequent recombination with electrons heavily favors the production of the 7(sup 3)S and 6(sup 3)D states of Hg, of which 7(sup 3)S is the upper level of the reported laser. For the neon laser, the dominant recombining ion has been previously shown to be Ne2(+). One of the dominant roles of helium in recombination lasers is inferred from the data for the neon laser at low helium concentrations. Helium appears to be necessary for the rapid relaxation of the electron energy which then increases the reaction rates for all known recombination processes thus increasing the pump rate into the upper state. Dissert. Abstr.

PROGRESS IN IMAGING MICROSCOPY WITH X RAY LASERS AT LLNL
L. B. DaSilva, J. E. Trebes, S. Mrowka, B. J. MacGowan, J. A. Koch, D. L. Matthews, T. W. Barbee, Jr., R. Balhorn, J. Gray, and E. Anderson et al 28 Jul. 1992 8 p Presented at the 3rd International Colloquium on X Ray Lasers, Schliersee, Germany, 18-22 May 1992
(Contract W-7405-eng-48)
(DE93-007508; UCRL-JC-111296; CONF-920523-7) Avail: CASI HC A02/MF A01

Imaging microscopy with short pulse (200 ps) x-ray lasers offers the opportunity of high resolution three-dimensional imaging of specimens in an aqueous environment without the blurring effects associated with natural motion and radiation induced chemical decomposition. As a first step towards this goal, we have performed imaging experiments with the Ni-like Ta x-ray laser (lambda=44.8 A) which have clearly resolved 500 A features on a gold test pattern. In addition, we have taken images of gold labeled dried rat sperm as a basis for comparison in future wet specimen imaging. The results of these experiments are described. DOE

SIMULTANEOUS DETERMINATION OF GAIN PARAMETERS IN STEADY STATE LASERS
C. C. Jensen, D. A. Branning, and R. D. Marchbanks 1993 9 p Presented at the 1992 International Conference on Lasers, Houston, TX, 7 Dec. 1992
(Contract W-7405-eng-36)
(DE93-007389; LA-UR-93-289; CONF-921256-1) Avail: CASI HC A02/MF A01

The optical gain parameters of pulsed steady-state lasers, such as dye and excimer lasers, are determined from a single set of experiments from either a laser oscillator or an amplifier. The gain parameters determined by this technique are the small-signal gain coefficient, the saturation intensity for stimulated emission, the saturation fluence for stimulated emission, and the non-saturable absorption coefficient. The measured saturation properties of laser amplifiers and oscillators are used in a data fitting routine that finds all of the gain parameters simultaneously. The values of the gain parameters are determined with greater accuracy than by the conventional methods of measuring each of the parameters individually. The knowledge of the values of all the gain parameters allows for the determination of fluorescence lifetime of a gain medium. DOE

INJECTION SEEDED, DIODE-PUMPED, SHORT PULSE Nd:YAG RING LASER FOR SPACE-BASED LASER RANGING Ph.D. Thesis
Donald Barry Coyle 1992 136 p
Avail: Univ. Microfilms Order No. DA9237217

In the near future, NASA plans to deploy LIDAR (Light Detection And Ranging) systems in space for the purpose of measuring geophysical quantities such as tectonic plate movement, crustal deformation near faults, and volcanic activity. Information on other quantities such as ice floes, cloud movemen t heights, and sea levels are also of interest. These measurements will require a spaceborne laser system which can operate unattended for extended periods of time and be able to make reliable sub-centimeter distance determinations from space. One system concept is the Geodynamic Laser Ranging System (GLRS) (Cohen et al. 1987). Optical pulses of 100 ps, or less, will be required from a Nd:YAG laser. The fundamental wavelength will provide altimetry information while the second and third harmonic frequencies will be generated to measure distances with high accuracy through two-color ranging techniques. Sub-100 ps pulses can be produced using either pulse pumped or continuous wave (CW) pumped mode-locked lasers. Shorter pulses are frequently achieved through CW pumping but the pulse energy is low, typically less than 10(exp -8) J. A method of achieving the pulse width of a CW mode-locked laser and pulse energy of a pulse pumped laser involves using regenerative amplification. The presented work covers one possible method of short pulse amplification. A pulsed Nd:YAG ring regenerative amplifier, pumped by laser diode-arrays and injection seeded by a 100 ps source, has been constructed. It was shown that high total optical gains can be achieved while holding the stringent alignment and timing specifications of regenerative amplification to a minimum. The construction of this laser/amplifier provided data on the behavior of 100 ps pulses when used as a temporal seed in a typical oscillator cavity with multiple optical surfaces. Dissert. Abstr.

COLLISIONAL RECOMBINATION LASERS Ph.D. Thesis
Damien Gerard Loveland 1992 195 p
Avail: Univ. Microfilms Order No. BRD-98051

An introduction to and extensive review of the field of strontium vapor recombination lasers is given. This includes coverage of both the theoretical aspects of the physics responsible for laser action and details of the technical features of a wide range of different laser designs. A description is given of an air-cooled strontium vapor laser of upgraded design which provides greater stability and improved ease of control over the output, together with increased running periods between the essential reloading of the strontium reservoir. A new type of design of strontium laser is investigated which employs water-cooling of the plasma tube, and it is shown that this is beneficial to obtaining increased output powers compared to natural-convection air-cooling the same laser, running at the same buffer gas pressure. Detailed experimental measurements are performed, of the electron temperature and strontium ion (Sr^+) excitation temperature in the immediate afterglow corresponding to the time of laser action, and of the spatially and temporally resolved electron density for the whole of the interpulse period. These experiments, which have not previously been attempted in such depth, provide an abundance of new data describing the properties of the discharge plasma of the strontium vapor laser. The use of strontium halides as an alternative to metallic strontium is also investigated. Dissert. Abstr.

EXPERIMENTAL AND THEORETICAL STUDY OF cw HF CHEMICAL LASER OVERTONE PERFORMANCE Ph.D. Thesis
David Leon Carroll 1992 337 p
Avail: Univ. Microfilms Order No. DA9236413

The overtone performance of the UIUC supersonic cw HF chemical laser was characterized as a function of flow rates, cavity pressure, mode volume, mirror reflectivity and method of He injection. The overtone performance was optimized by the same set of flow rates that optimized the fundamental performance. When the absorption/scattering losses of the mirrors were taken into account, an overtone efficiency of 70-90 percent was achieved, which is the highest reported to date. The overtone efficiency was a strong function of media saturation. There was no significant change in overtone power and efficiency as the mode volume increased. However, there were an increase in the number of lasing lines and a shift to higher J lines. Overtone performance was as sensitive to cavity pressure as fundamental performance. There was no significant change in overtone efficiency when the method of the injection was changed. Base region absorption by ground state HF has a significant effect on fundamental and overtone performance. Even with very high degrees of saturation, approximately 10 percent of the total power was lost when the He purge was turned off. For a laser having an extensive data base with well characterized mirrors to firmly establish the Rigrod parameters g(0) and I(sat), the accuracy to which the mirror reflectivities can be deduced using measured mirror transmissivities, measured outcoupled power and Rigrod theory is approximately plus or minus 0.07 percent for high reflectivity overtone mirrors. Rigrod theory shows that a higher media saturation yields a higher overall overtone efficiency, but does not necessarily yield a higher measurable power (power in the bucket). For low absorption/scattering loss overtone mirrors and a 5 percent penalty in outcoupled power, the intracavity flux and hence the mirror loading can be reduced by more than a factor of two when the gain length is long enough to well saturate the media. The inclusion of HF-H2 multi-quantum VV transfer reactions in the ORNECL model significantly improved the prediction of the zero power gains for the H2 rich UI supersonic laser. The inclusion of absorption by SFx molecules in the model significantly improved the prediction of the Fabry-Perot spectra. Dissert. Abstr.

EXPERIMENTAL AND THEORETICAL STUDY OF CW HF CHEMICAL LASER RESIDUAL FUNDAMENTAL GAIN Ph.D. Thesis
Panagiotis Theodoros Theodoropoulos 1992 354 p
Avail: Univ. Microfilms Order No. DA9236606

A new technique that uses a multi-line probe beam to measure the gain on several lines simultaneously was developed. This new technique was used to measure the gains of the peak fundamental lines P1(4-9) and P2(4-9) while lasing on the overtone, for three levels of media saturation. The suppression of the fundamental gains obtained at relatively high media saturation with 99.7/99.7 percent reflective mirrors was essentially the same as that obtained with 55 percent higher intracavity flux with 99.8/99.8 percent reflective mirrors. The gains of the low J lines P1(4-6) and P2(4-6) were suppressed 41 percent to 84 percent; the gains of the high J lines P1(7-9) and P2(7-9) were suppressed 3 percent to 43 percent. The 1 to 0 lines were suppressed more than the 2 to 1 lines. The maximum suppression occurred between 2 and 6 mm downstream from the nozzle exit plane, near the center of the 9 mm overtone beam. Simulation of the experiments with a rotational nonequilibrium computer model showed that the fundamental gains are determined by three independent mechanisms when lasing occurs on the overtone. First, overtone lasing decreases the gains of the P1(J) and P2(J) lines whose upper or lower levels are directly involved in P20(J) overtone lasing. Second, overtone lasing reduces the rate at which the low J v = 2 states are populated by rotational relaxation and increases the rate at which the low J v = 0 states are populated by rotational relaxation, resulting in suppression of the low J fundamental gains whose upper or lower levels are not directly involved in overtone lasing. Third, overtone lasing reduces the rate at which the HF(0,J) and HF(1,J) states are populated by the various collisional deactivation processes. With 10 percent of the original rotational relaxation rate, the computer model was in reasonable agreement with the measured zero power gain profiles. The model overpredicted the fundamental gain suppression (Delta alpha) for the P1(8,9) and P2(8,9) lines whose upper or lower levels were directly involved in overtone lasing, and underpredicted the suppression for lines P1(4) and P2(4,5). The model predicted the suppression for lines P1(5-7) and P2(6,7) reasonably well. With the original rotational relaxation rate, the model was in reasonable agreement with the measured suppression of all P1(4-9) and P2(4-9) lines. However, with the original RR rate, the model's agreement with the experimental zero power gain profiles was not adequate. Dissert. Abstr.

GENERATION OF ACOUSTIC WAVES BY FOCUSED INFRARED NEODYMIUM-LASER RADIATION Ph.D. Thesis
Barry Ward 1991 295 p
Avail: Univ. Microfilms Order No. BRDX98211

When the radiation from a sufficiently powerful pulsed laser is focused into the transparent gaseous, liquid or solid media, dielectric breakdown may occur around the beam waist giving rise to a short-lived high-temperature plasma which quickly heats the surrounding material. As a consequence of various energy-coupling mechanisms, this phenomenon causes the emission of one or more high-frequency ultrasonic acoustic waves whose speeds of propagation are dependent upon the physical properties of the host medium. In the high-speed photographic studies described, the 1.06 micron near-infrared radiation from an 8-ns, 10-mJ Q-switched Nd:YAG laser is focused in or onto a variety of fluid and solid materials. The rapid variations in density around the resulting plasma events are visualized using a Mach-Zehnder interferometer with a sub-nanosecond dye-laser light source and a video-imaging system. Calculations of the corresponding transient pressure distributions are then enacted from the digitally-recorded interferograms using a semi-automatic procedure under the control of a personal computer. Measurements of position, displacement, and velocity are also carried out using the same optical apparatus in schlieren and focused shadowgraph high-speed photographic measurements. The experimental work outlined in the following chapters is divided into three broad fields of interest. In the first of these, a study of the laser-generation of spherical shock waves in atmospheric air is carried out. In the second, the neodymium-laser beam is focused onto different solid-fluid interfaces resulting in the formation of bulk longitudinal and shear waves and surface acoustic waves. The interactions of these waves with various obstacles and defects are investigated with reference to their application to non-destructive testing. In the third and most important field, a detailed study of the dynamics of laser-induced cavitation bubbles in water is carried out. With regard to the associated phenomenon of cavitation erosion, particular attention is paid to the formation of spherical acoustic waves by radially-oscillating vapor cavities at various distances from transparent rigid boundaries. Dissert. Abstr.

TIME RESOLVED STUDIES OF IN-WELL AND CROSS-WELL CARRIER TRANSPORT IN MQW SEMICONDUCTOR STRUCTURES Final Report, 15 May 1991 - 30 Sep. 1992
Alan Miller 8 Dec. 1992 33 p
(Contract DAAL03-91-G-0133)
(AD-A261170; ARO-28594.5-EL) Avail: CASI HC A03/MF A01

The objective of this research project was to establish a better understanding of in-well and cross-well carrier transport in multiple quantum well (MQW) semiconductors. Carrier emission from both multiple and single quantum well devices have been studied in detail in p-i-n doped MQW SEED-type modulator structures and in waveguides. Simultaneous measurements of electron and hole emission rates has been accomplished for the first time leading to important conclusions concerning thermionic emission models for quantum wells. Extensive modeling of the dynamical optical response relating to cross-well carrier transport has been carried out. Spin relaxation has also been used successfully to monitor carrier dynamics in MQW devices. A new family of mode-locked lasers have been developed for time resolved measurements which are looking extremely attractive as ultrashort pulse sources for GaAs-based optoelectronic devices. DTIC

LIQUID CRYSTALS FOR LASER APPLICATIONS
S. D. Jacobs, K. L. Marshall, and A. Schmid 14 Oct. 1992 108 p
(Contract DAAL03-92-G-0147)
(AD-A261209; ARO-30367.2-PH-UIR) Avail: CASI HC A06/MF A02

This article highlights some of the advances made in the use of liquid crystals for laser applications from 1982 through 1992. New materials and new effects were discovered, many new devices were developed, and novel applications for well-understood phenomena were conceived. This was quite an eventful time period. Several new books were published on the broad subject of LC's, and the international scientific community organized a society devoted to encouraging further scientific and educational advancement in the field. Attention was focused on LC's in October of 1991 when the Nobel Prize in Physics was awarded to Pierre-Gilles de Gennes for his pioneering work toward understanding order phenomena in LC's and polymers. This article is divided into four sections. The first section discusses new materials, specifically ferroelectric LC's and LC polymers. The former have opened up the realm of submicrosecond response for LC devices, and the latter have significantly reduced the sensitivity of LC optics to temperature. Some new insights into the optical properties of materials are also mentioned. The second section reviews new developments in passive applications for cholesterics and nematics. Included here are the fabrication of cholesteric laser mirrors and apodizers, the use of LC polymers for notch filters and as optical storage media, and some novel nematic retarder concepts such as the distributed polarization rotator. LASER PROPAGATION THROUGH TURBULENCE Final Technical Report, Sep. 1990 - Sep. 1992
Anna Consortini Nov. 1992 75 p
(Contract DAJA45-90-C-0029)
(AD-A260712; R/D-6458-EE-01) Avail: CASI HC A04/MF A01

A large data base of intensity fluctuations of laser radiation through the turbulent atmosphere has been analyzed. The base had been previously obtained in a joint measurement campaign of the Department of Physics, University of Florence, Italy, and the Wave Propagation Laboratory of NOAA/ERL, Boulder, Colorado, U.S.A. It included good quality data collected through continuously evolving atmospheric turbulence, comprising low,

moderate and high turbulence levels, as well as structure parameter (the so called structure constant) and inner scale, values, simultaneously measured. Results have been obtained on the four topics of the present contract. (1) The effect of the inner scale of the turbulence on the normalized variance of the intensity (scintillation index) was experimentally demonstrated, for the first time. Plots of intensity variance versus structure parameter, for fixed ranges of the inner scale, allowed an experimental determination of the role played by inner scale and structure parameter. They constitute a reference for comparison with results from theory or numerical simulations. (2) The evolution of the probability distributions with changing propagation conditions was examined. Some comparisons with existing theoretical distributions were made. Necessity for further investigation resulted. (3) A numerical deconvolution procedure was developed, to remove a broad noise from intensity fluctuation histograms, and applied to low intensity data measured with very small apertures. The results were positive (4) Spectral analyses of experimental data as well as time correlations of intensity fluctuations were made. The contribution to scintillation of the high frequency components, related to the wave coherence length, was shown. DTIC

LOSS OF TEMPORAL COHERENCE OF LASER LIGHT PROPAGATED THROUGH SIMULATED COASTAL WATERS Interim Report, FY92

N. L. Swanson Jan. 1993 26 p

(AD-A261303; CSS-TM-627-92) Avail: CASI HC A03/MF A01

Research is currently underway to investigate the physical mechanisms that cause loss of temporal coherence in scattered light. The results of experiments that measure coherence length versus temperature, optical path length, and water quality are reported. It is shown that the loss of temporal coherence is caused by spectral broadening. Based on these results and research into the causes of spectral broadening, experiments are proposed to measure each type of broadening mechanism, with a much higher degree of accuracy. DTIC

EFFICIENT NONLINEAR OPTICAL CONVERSION OF 1.319-MICRON LASER RADIATION

Robert L. Byer and Robert C. Eckardt 14 Jan. 1993 14 p

(Contract DAAL03-89-K-0155)

(AD-A261309; ARO-27418.4-PH) Avail: CASI HC A03/MF A01

The accomplishments of this program are in the development and application of periodically poled nonlinear optical materials for nonlinear frequency-conversion. We have demonstrated the use of periodically poled lithium niobate (PPLN) as a bulk material for external resonant cavity second-harmonic generation with continuous-wave (cw) output power of 1.7 W. Work that is following this investigation is showing that planar waveguides of PPLN may well be the most satisfactory method of generation of 10's of mW of the 659-nm harmonic of the 1.32-micrometer Nd:YAG laser. We encountered major obstacles obtaining multilayer dielectric coatings necessary to pursue our proposed design of monolithic bulk optical harmonic generators. Additional alternative approaches such as discrete component resonant second harmonic generation employing single domain and periodically poled bulk crystals and monolithic single domain resonators formed by total internal reflection remain under investigation. START-UP IMPRINTING AND SHOCK DYNAMICS IN LASER-TARGET INTERACTION Interim Report

Mark H. Emergy 10 Dec. 1992 27 p

(NR Proj. 8068)

(AD-A261384; NRL/MR/6440-92-7174) Avail: CASI HC A03/MF A01

Improved uniformity of the laser for-al spot profile is a necessary criterion for the success of high intensity laser fusion and to improve the quality of data from moderate intensity laser driven shock experiments in solids. Recently developed laser smoothing techniques rely on both temporal smoothing and thermal smoothing to produce uniform ablation pressures on the target surface. Thermal smoothing is not effective during the low intensity portion of a laser pulse and the resultant shock structure mirrors the residual laser nonuniformities. The impact of the first (nonuniform) shock can be diminished by using foam layers, a precursor flash, shallow angles of incidence, and by adiabatically compressing the target with a temporally long, slowly rising laser pulse. FEASIBILITY EXPERIMENT FOR SODIUM-LAYER LASER GUIDE STARS AT THE LAWRENCE LIVERMORE NATIONAL LABORATORY

C. Max, K. Avicola, H. Bissinger, J. Brase, D. Gavel, H. Friedman, J. Morris, S. Oliver, J. T. Salmon, and K. Waltjen Mar. 1992 9 p Presented at the Laser Guide Star Adaptive Optics Workshop, Albuquerque, NM, 10-12 Mar. 1992

(Contract W-7405-eng-48)

(DE93-007115; UCRL-JC-109526; CONF-9203139-3) Avail: CASI HC A02/MF A01

We are developing a feasibility experiment to demonstrate closed-loop adaptive optics using a sodium-layer laser guide star. We will use the copper-vapor-pumped dye lasers developed for LLNL's Atomic Vapor Laser Isotope Separation Program to create the laser guide star. Closed-loop adaptive corrections will be accomplished using a 69-subaperture adaptive optics system on a one-meter telescope at LLNL. The laser beam will be projected upwards from a beam director approximately 5 meters away from the main telescope, and is expected to form a spot about a meter in diameter at the atmospheric sodium layer (at an altitude of 95 km). Details of the adaptive optics components and an analysis of the expected performance will be presented in companion papers for this Workshop. Here we summarize the overall architecture and system objectives. The long-term goal of our effort is to develop laser guide stars and adaptive optics for large astronomical telescopes. DOE

FALCON NUCLEAR-REACTOR-PUMPED LASER PROGRAM AND WIRELESS POWER TRANSMISSION

R. J. Lipinski and P. S. Pickard 1992 11 p Presented at the 1st Annual Wireless Power Transmission Conference, San Antonio, TX, 23-25 Feb. 1993

(Contract DE-AC04-76DP-00789)

(DE93-007607; SAND-92-1973C; CONF-930258-1) Avail: CASI HC A03/MF A01

FALCON is a high-power, reactor-pumped laser concept. The major strengths of a reactor-pumped laser are as follows: (1) simple, modular construction; (2) long-duration, closed-cycle capability; (3) self-contained

power; (4) compact size; and (5) a variety of wavelengths (from visible to infrared). Reactor-pumped lasing has been demonstrated experimentally in various mixtures of xenon, argon, neon, and helium at wavelengths of 585, 703, 725, 1271, 1733, 1792, 2032, 2630, 2650, and 3370 nm with intrinsic efficiency as high as 2.5 percent. Powers up to 300 W for 2 ms have been demonstrated. Projected beam quality for FALCON is good enough that frequency doubling at reasonable efficiencies could be expected to yield wavelengths at 353, 363, 636, 867, 896, 1016, 1315, 1325, and 1685 nm. Appropriate missions for FALCON are described and include the following: power beaming to satellites, the moon, and unmanned surveillance planes; lunar mapping; space debris removal; and laser propulsion. VERY LOW FREQUENCY SIGNALS AND WHISTLER-MODE AMPLIFICATION IN THE MAGNETOSPHERE AND LIMIT-CYCLE BEHAVIOR IN THE CECAF INFRARED FREE ELECTRONIC LASER M.S. Thesis
Daryl L. Caudle Dec. 1992 113 p
(AD-A261776) Avail: CASI HC A06/MF A02

Very low frequency (VLF) electromagnetic wave injection experiments were conducted on 23-24 Jan. 1988 from a 42-km horizontal dipole antenna located at Siple Station, Antarctica. The experiment consisted of a diagnostic format transmitted for one minute every five minutes, for a 10 hour period between 1700 UT and 0300 UT. These signals were received and recorded at the conjugate magnetic field point location at Lake Mistissini, Canada. A detailed analysis of this data clearly demonstrates hot plasma effects such as saturated power levels, exponential growth rates, sideband formation, and triggered emissions due to wave-particle interactions. These hot plasma effects remain constant over a time scale of 30 seconds but show large variations over a time scale of 5 minutes. These VLF signals were used to simulate whistler waves which occur naturally and are amplified by energetic electrons spiraling around magnetic field lines near the geomagnetic equator. Navy VLF communications are strongly affected by the presence of whistler waves. The electron and whistler wave interaction can be described by a theoretical model which is very similar to that used for free electron lasers (FEL). DTIC

GLOBAL DYNAMIC MODELING OF A TRANSMISSION SYSTEM Final Report
F. K. Choy (Akron Univ., OH.) and W. Qian (Akron Univ., OH.) Apr. 1993 163 p
(Grant NAG3-900; RTOP 505-62-10)
(NASA-CR-191117; E-7731; NAS 1.26:191117; ARL-CR-11) Avail: CASI HC A08/MF A02

The work performed on global dynamic simulation and noise correlation of gear transmission systems at the University of Akron is outlined. The objective is to develop a comprehensive procedure to simulate the dynamics of the gear transmission system coupled with the effects of gear box vibrations. The developed numerical model is benchmarked with results

from experimental tests at NASA Lewis Research Center. The modal synthesis approach is used to develop the global transient vibration analysis procedure used in the model. Modal dynamic characteristics of the rotor-gear-bearing system are calculated by the matrix transfer method while those of the gear box are evaluated by the finite element method (NASTRAN). A three-dimensional, axial-lateral coupled bearing model is used to couple the rotor vibrations with the gear box motion. The vibrations between the individual rotor systems are coupled through the nonlinear gear mesh interactions. The global equations of motion are solved in modal coordinates and the transient vibration of the system is evaluated by a variable time-stepping integration scheme. The relationship between housing vibration and resulting noise of the gear transmission system is generated by linear transfer functions using experimental data. A nonlinear relationship of the noise components to the fundamental mesh frequency is developed using the hypercoherence function. The numerically simulated vibrations and predicted noise of the gear transmission system are compared with the experimental results from the gear noise test rig at NASA Lewis Research Center. Results of the comparison indicate that the global dynamic model developed can accurately simulate the dynamics of a gear transmission system. Author (revised)

POSITION AND FORCE CONTROL OF A VEHICLE WITH TWO OR MORE STEERABLE DRIVE WHEELS
D. B. Reister and M. A. Unseren 1992 20 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE92-041301; CONF-930519-2) Avail: CASI HC A03/MF A01

When a vehicle with two or more steerable drive wheels is traveling in a circle, the motion of the wheels is constrained. The wheel translational velocity divided by the radius to the center of rotation must be the same for all wheels. When the drive wheels are controlled independently using position control, the motion of the wheels may violate the constraints and the wheels may slip. Consequently, substantial errors can occur in the orientation of the vehicle. A vehicle with N drive wheels has (N - 1) constraints and one degree of freedom. We have developed a new approach to the control of a vehicle with N steerable drive wheels. The novel aspect of our approach is the use of force control. To control the vehicle, we have one degree of freedom for the position on the circle and (N - 1) forces that can be used to reduce errors. Recently, Kankaanranta and Koivo developed a control architecture that allows the force and position degrees of freedom to be decoupled. In the work of Kankaanranta and Koivo the force is an exogenous input. We have made the force endogenous by defining the force in terms of the errors in satisfying the rigid body kinematic constraints. We have applied the control architecture to the HERMIES-M robot and have measured a dramatic reduction in error (more than a factor of 20) compared to rations without force control. DOE

APPARATUS AND METHODS FOR DETERMINING BALANCE OF A CYLINDRICAL VEHICLE Patent
David M. Nugent, inventor (to Navy) 8 Dec. 1992 11 p Filed 28 Aug. 1991
(AD-D015637; US-Patent-5,168,749; US-Patent-Appl-SN-750998) Avail: US Patent and Trademark Office

Apparatus and methods for determining balance of a cylindrical vehicle are presented. The apparatus comprises a frame adapted for horizontal disposition, first and second support assemblies mounted on the frame for receiving the vehicle, first and second load cells mounted, respectively, on the first and second support assemblies. Upon placement of the vehicle on the support assemblies, the load cells are adapted to provide readings indicative of the weight of the vehicle. From these readings, the center of gravity of the vehicle may be determined . A torsion cell assembly is mounted on the frame and adapted for connection to the vehicle and for providing indications of righting moment and static heel of the vehicle.

TURBINE TURBOBRAKE SYSTEMS Ph.D. Thesis
Michael I. Goodisman 1991 253 p
Avail: Univ. Microfilms Order No. BRD-98278

Short duration rotating turbine facilities are a recent development in the field of turbine research. Turbine braking devices can be used to maintain the turbine at the desired test speed, resulting in a longer usable test time. The Isentropic Light Piston Cascade at the Defence Research Agency in Pyestock will perform heat transfer and aerodynamic tests on the first stage of a Rolls-Royce turbine (MT1) linked to a new type of brake, the 'axial turbo brake'. The axial turbo brake is driven by the turbine's exhaust gas and is isolated from the turbine by a choked throat. The turbo brake's power absorption must be controlled to match the power developed by the turbine stage for a constant speed run. Both the turbo brake blade shape and novel power control system were developed from tests on a 0.17 scale test rig. The turbo brake's braking is controlled through by-pass of flow over the blade tips and partial blockage of the turbo brake's exit annulus. Also described is the mechanical design, development and manufacture of the full size turbo brake, turbine disc and turbine blades, which have been successfully spun tested to their overspeed condition. Finally, a theory for self-pumping turbo brakes is developed. These devices would have additional applications because they do not require a supply of high pressure gas to drive them. Dissert. Abstr.

FORMULATION AND TREATMENT OF FRICTIONAL CONTACT PROBLEMS USING FINITE ELEMENTS Ph.D. Thesis
Tod Alan Laursen 1992 209 p
Avail: Univ. Microfilms Order No. DA9302237

In recent years, problems involving the mechanical contact between deformable bodies have received increasing attention from the computational solid mechanics community. Such problems, usually called contact problems, are particularly challenging in the presence of large deformations and inelastic response, as are found, for example, in dynamic impacts between bodies, metal forming applications, mechanical (hardness) testing, and post buckling response. The introduction of friction is an additional complication which has important consequences, both in the underlying mathematical structure of the problem and in the design of efficient solution algorithms. In this work, a new comprehensive approach is presented which enables the solution of frictional contact problems within a Lagrangian framework. The approach is suitable for the solution of static or low frequency dynamic problems using implicit time integration. Novel features of the work include: (1) a continuum basis for the formulation, making it suitable for arbitrary discretizations and two or three spatial dimensions; (2) the presence of an exact linearization for the discrete global equations, such that optimal convergence properties are attained when using a Newton-Raphson strategy for solving the nonlinear equation system; and (3) penalty and augmented Lagrangian enforcement of constraints, leading to efficient solution of the global equations while circumventing ill-conditioning. The augmented Lagrangian treatment presented includes a reliable algorithmic symmetrization of the frictional response, lending the formulation a high level of compatibility with existing structural and solid mechanics finite element codes. In presenting the proposed formulation, many details of the discretization process are given, including explicit expressions for the contact contributions to the global equation system. A full set of numerical simulations, demonstrating the utility of the proposed methodology, is also presented. Dissert. Abstr.

A CONTROL STRUCTURE FOR FAULT-TOLERANT OPERATION OF ROBOTIC MANIPULATORS
Yung Ting, S. Tosunoglu, and D. Tesar 1993 8 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-FG02-86NE-37966)
(DE93-005783; DOE/NE-37966/2; CONF-930519-7) Avail: CASI HC A02/MF A01

Failure of any component of a robotic system during operation is a matter of concern. This work investigates internal shock phenomena due to the failure of joint actuation, and a recovery algorithm for both serial and parallel mechanisms under such circumstances. A control algorithm is studied that consists of a model reference algorithm and computed torque method in the feedforward process, and a simple PID controller in the feedback process. Simulation results illustrate the effectiveness of this recovery algorithm which attempts to reduce the internal shock when failure occurs, and accomplish the tracking of the given end-effector trajectory.

The outlined recovery algorithms, which include two stages of robot control, path planning and path tracking, are expected to be applied not only to a case where some joint is fully failed, but also to cases where some joints experience partial failure. DOE

LASER WELDING OF SELECTED AEROSPACE ALLOYS Ph.D. Thesis
Gracie E. Ebadan 1989 331 p
Avail: Univ. Microfilms Order No. BRDX98033

The study was aimed at developing an understanding of the microstructural effects of the laser welding process on the alloys, and assessing the structural integrity of the resultant welds. The effect of laser processing parameters such as laser power, laser beam traverse speed, lens focal length, and the manipulation of these parameters on the welding efficiency and weld area integrity was also investigated. Other tasks within the project included a study on the possibility of using an anodic film to enhance the laser weld ability of Al 6061. Finally, attempts were made to identify phases observed in the weld area of the composite materials. Nimonics C263 and PE11 exhibited laser welds free of cracks and porosity. The difference in composition between the two alloys did not result in any significant dissimilarities in their response to the laser welding process. The welds in both alloys exhibited a fine columnar dendritic microstructure, and while carbides were observed in the interdendritic regions of the welds, electron optical analysis did not reveal any gamma' precipitates in this region. It was concluded that for the welding of thin gage materials above a threshold laser power the resultant welding efficiency shows a greater dependence on laser beam mode, and laser spot size, than on laser power, and beam traverse speed. Aluminum 6061 was not easily welded with a laser in its as received form, and the welds showed some degree of porosity. Anodizing was found to improve the welding efficiency in this material. While the presence of an anodic film on the metal surface increased the welding efficiency of the alloy, no relationship was found between the thickness of the anodic film and welding efficiency in the range of film thicknesses investigated. Weld regions were observed to be cellular dendritic in structure, with narrow heat affected zones. No precipitates or low melting point phases could be identified in the weld region. Melt zones were successfully produced in the composite materials, with the main problem encountered being that of porosity adjacent to the weld bead. It was shown that manipulation of the laser welding parameters resulted in a decrease in this porosity. Dissert. Abstr.

NUMERICAL KINEMATIC TRANSFORMATION CALCULATIONS FOR A PARALLEL LINK MANIPULATOR
S. M. Killough 1993 8 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-005778; CONF-930519-8) Avail: CASI HC A02/MF A01

Parallel link manipulators are often considered for particular robotic applications because of the unique advantages they provide. Unfortunately, they have significant disadvantages with respect to calculating the kinematic transformations because of the high-order equations that must be solved. A manipulator design that exploits the mechanical advantages of parallel links yet also has a corresponding numerical kinematic solution that can be solved in real time on common microcomputers is presented. EVALUATION OF A VIBRATION DIAGNOSTIC SYSTEM FOR THE DETECTION OF SPUR GEAR PITTING FAILURES
Dennis P. Townsend and James J. Zakrajsek Jun. 1993 11 p Proposed for presentation at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by the AIAA, SAE, ASME, and ASEE
(DA Proj. 1L1-62211-A-47-A; RTOP 505-62-10)
(NASA-TM-106103; E-7752; NAS 1.15:106103; AIAA Paper 93-2298; ARL-TR-11) Avail: CASI HC A03/MF A01

A vibration diagnostic system was used to detect spur gear surface pitting fatigue in a closed-loop spur gear fatigue test rig. The diagnostic system, comprising a personal computer with an analog-to-digital conversion board, a diagnostic system unit, and software, uses time-synchronous averaging of the vibration signal to produce a vibration image of each tooth on any gear in a transmission. Several parameters were analyzed including gear pair stress wave and raw baseband vibration, kurtosis, peak ratios, and others. The system provides limits for the various parameters and gives a warning when the limits are exceeded. Several spur gear tests were conducted with this system and vibration data analyzed at 5-min. intervals. The results presented herein show that the system is fairly effective at detecting spur gear tooth surface fatigue pitting failures. Author

EVALUATION OF THE MIGRATING COMBUSTION CHAMBER (MCC) ENGINE Final Report
K. M. Miller and Dorin Morar Jan. 1993 43 p
(AD-A260780; BRDEC-2538) Avail: CASI HC A03/MF A01

The Belvoir Research, Development and Engineering Center (BRDEC) tested three Migrating Combustion Chamber (MCC) engines built by Engine Research Associates (ERA) for Natick RD and E Center. The MCC concept attempts to provide a lightweight, quiet engine having a cool exhaust gas stream. The cool exhaust is attained by capturing additional energy from expansion beyond that achievable in conventional engines by the use of gas porting to multiple expansion chambers; this provides a more efficient engine operation than is otherwise attainable for the configuration. The testing included determining the engine torque-speed-power characteristics and the Brake Specific Fuel Consumption (BSFC) under a variety of load conditions. Startability and operability were concerns; starting under normal ambient conditions was difficult. All testing was performed using a 10:1 fuel/oil mixture of low lead gasoline with AMZOIL synthetic lubricating oil for two-stroke engines. The maximum power achieved was 0.25 horsepower at 4,400 rpm. The peak torque observed was 69 oz.-in. at 3,200 rpm. It was not possible to make noise and vibration measurements during the testing cycle, but they appeared to be low. The MCC engines tested had relatively short lives, operating for less than 25 hours. Performance and durability improvements are necessary before this MCC design can be considered as a viable alternative to commercially available two-cycle engines. DTIC

BIPED CONTROL VIA NONLINEAR DYNAMICS Ph.D. Thesis
Hatem M. Hmam 1992 188 p
Avail: Univ. Microfilms Order No. DA9302395

This thesis applies nonlinear techniques to actuate a biped system and provides a rigorous analysis of the resulting motion. From observation of human locomotion, it is believed that the 'complex' dynamics developed by the aggregation of multiple muscle systems can be generated by a reduced order system which captures the rough details of the locomotion process. The investigation is begun with a simple model of a biped system. Since the locomotion process is cyclic in nature, we focus on applying the topologically similar concept of limit cycles to the simple model in order to generate the desired gaits. A rigorous analysis of the biped dynamics shows that the controlled motion is robust against dynamical disturbances. In addition, different biped gaits are generated by merely adjusting some of the limit cycle parameters. More dynamical and actuation complexities are then added for realism. First, two small foot components are added and the overall biped motion under the same control actuation is analyzed. Due to the physical constraints on the feet, it is shown using singular perturbation theory how the gross behavior of the biped dynamics are dictated by those of the reduced model. Next, an analysis of the biped dynamics under added nonlinear elasticities in the legs is carried out. Moreover, using a slightly modified model, forward motion is generated in the sagittal plane. At each step, a small amount of energy is consistently derived from the vertical plane and converted into a forward motion. Stability of the forward dynamics is guaranteed by appropriate foot placement. Finally, the robustness of the controlled biped dynamics is rigorously analyzed and illustrated through extensive computer simulations. Dissert. Abstr.

N93-25727 Salford Univ. (England).
THE INDUCTION OF ELASTIC FINE MOTION IN ROBOTIC GRASPS Ph.D. Thesis
Abdul Ghafoor 1992 283 p
Avail: Univ. Microfilms Order No. BRD-98219

The purpose of this thesis is to explore the possibilities of inducing elastic fine motions to the object held by a robotic gripper through a number of contacts. The problems of grasping are discussed explicitly to establish basis of imparting fine motions to the grasped objects. The recent studies in grasping and manipulation have suggested different kinds of models of the contacts between the grasped object and the gripping devices. Amongst those, the point contacts have commonly been used in grasping. Depending upon the nature of the objects and the contacts, further surface properties such as friction need to be analyzed. The analysis of these types of grasps are statically indeterminate. There is a need for a simple and general technique by which we are able to establish and analyze a statically indeterminate grasp. The use of the theory of elasticity in the form of elastic finger-tips solves the indeterminacy of the grasping problems. The compression of elastic systems in the finger-tips by the application of appropriate preloads provides a means of inducing fine movements to the grasped rigid objects. The contact elasticity is exploited in achieving this, while at the same time ensuring that the grasp is maintained. In the most general case, it may not always be possible to achieve a particular defined fine motion of the grasped object. In such cases approximate solutions are demonstrated. Many examples related to the basis of the theoretical analysis are also discussed. These cover the grasp of the objects and the induction of fine motion of the grasped objects, by considering elastic point contacts with and without friction. The analysis presented in this thesis is mainly based upon the assumption of point contacts, but a comparison between point contacts and cluster (a combination of point contacts) is also included. A brief description is also given of the preliminary experiments which were designed to demonstrate practically the induction of fine motions by the application of preloads through the normals of the elastic contacts. The experiments confirm the theoretical results.

ANALYSIS AND DESIGN OF A NOVEL ROBOTIC FINGER-TIP SENSOR FOR ADAPTIVE GRASPING Ph.D. Thesis

M. K. Mortazavi 1991 303 p

Avail: Univ. Microfilms Order No. BRD-98234

The need arises in a robotic grasping environment to determine in a non-contact manner the distance of the surface to be grasped and its relative orientation from a robot finger-tip. The research described deals with the design and development of a system to solve this problem. The investigation was developed in four major stages. Initially, a practical study of robotic grasping instrumentation problems and methods of grasping and the limitation of instrumentation of conventional robot grippers was carried out. The purpose was to explore a suitable technique to identify the direction of the contact normal to the surface to be contacted in relation to the known orientation of grasping device. Next, a theory supporting an optical robotic sensor was developed in both principle and practices. The method involves projection of three collimated beams diverging from central finger-based reference direction towards the object which is assumed to have locally flat surface. A geometric model relates the position of three light points on the object surface to surface orientation and to the distance between the object and the finger-tip and vice-versa. In order to measure the position of light beams intersecting a given test surface, a number of light-beam producing techniques using incandescent and laser sources, and then detecting the resulting projection points by sensing elements were investigated. Feasible operational ranges of distance and orientation parameters for the laser and photo-detectors were established. These parameters were used to demonstrate and evaluate the feasibility and applicability of the proposed theory with reference to the accuracy of the direction of the contact normal. Dissert. Abstr.

PASSIVITY MOTIVATED CONTROLLER DESIGN FOR FLEXIBLE STRUCTURES

Declan Hughes and John T. Wen 18 Jan. 1993 25 p

(Contract DAAL03-92-G-0123)

(AD-A261122; ARO-30378.1-EG-URI) Avail: CASI HC A03/MF A01

When actuators and sensors on a controlled mechanical structure form naturally passive pairs, which usually requires physical collocation, very robust stabilizing controllers can be constructed. If the number of such naturally passive pairs is small, the closed loop performance may not be satisfactory. To address this problem, additional sensors, which are usually cheaper, lighter, and easier to instrument than actuators are frequently added to the control system. However, the passivity properly no longer holds for these sensors with respect to the existing actuators. This paper presents some results on extending the passivity based design to incorporate these noncollocated sensors by using some nominal model information to synthesize a fictitious strictly passive output. The design approach was applied to a single rotating flexible beam with encouraging results. DTIC

An outer race carrier is constructed for receiving an outer race of an antifriction bearing assembly. The carrier in turn is slidably fitted in an opening of a support wall to accommodate slight axial movements of a shaft. A plurality of longitudinal splines on the carrier are disposed to be fitted into matching slots in the opening. A deadband gap is provided between sides of the splines and slots, with a radial gap at ends of the splines and slots and a gap between the splines and slots sized larger than the deadband gap. With this construction, operational distortions (slope) of the support wall are accommodated by the larger radial gaps while the deadband gaps maintain a relatively high springrate of the housing. Additionally, side loads applied to the shaft are distributed between sides of the splines and slots, distributing such loads over a larger surface area than a race carrier of the prior art.

The present invention provides a pneumatically powered actuator having hydraulic control for both locking and controlling the velocity of an output rod without any sponginess. The invention includes a double-acting pneumatic actuator having a bore, a piston slidably engaged within the bore, and a control rod connected to the piston. The double-acting pneumatic actuator is mounted to a frame. A first double-acting hydraulic actuator having a bore, a piston slidably engaged within the bore, and a follower

rod mounted to the piston is mounted to the frame such that the follower rod is fixedly connected to the control rod. The maximum translation of the piston within the bore of the first double-acting hydraulic actuator provides a volumetric displacement V1. The present invention also includes a second double-acting hydraulic actuator having a bore, a piston slidably engaged within the bore, and an output rod mounted to the piston. The maximum translation of the piston within the bore of the second double-acting hydraulic actuator provides a volumetric displacement V2, where V2=V1. A pair of fluid ports in each of the first and second double-acting hydraulic cylinders are operably connected by fluid conduits, one of which includes a valve circuit which may be used to control the velocity of the output rod or to lock the output rod in a static position by regulating the flow of hydraulic fluid between the double-acting cylinders. A SURFACE INTEGRAL ALGORITHM FOR THE MOTION PLANNING OF NONHOLONOMIC MECHANICAL SYSTEMS M.S. Thesis
David P. Anderson Dec. 1992 66 p
(AD-A261746) Avail: CASI HC A04/MF A01

The number of coordinates needed to completely describe the configuration of a holonomic mechanical system is equal to the number of degrees of freedom possessed by that system. In contrast, nonholonomic systems always require more coordinates for their description than their degrees of freedom due to the nonintegrable nature of the governing velocity constraints. The task of nonholonomic motion planning applied to a given system is to develop trajectories of the independent coordinate variables such that the entire system is driven to some desired point in its configuration space. An algorithm for constructing these trajectories is presented. In this algorithm, the independent variables are first converged to their desired values. The dependent variables are subsequently converged using closed trajectories of the independent variables. The requisite closed trajectories are planned using Stoke's Theorem which converts the problem of finding a closed path in the space of the independent variables to that of finding a surface area in that same space such that the dependent variables converge to their desired values as the independent variables traverse along the boundary of the surface area. The use of Stoke's Theorem simplifies the motion planning process and also answers important questions pertaining to the system. The salient features of the algorithm are apparent in the two examples discussed: a planar space robot and a disk rolling without slipping on a flat surface. DTIC

Avail: CASI HC A15/MF A03

Increased emphasis on energy efficiency and air quality has resulted in a number of state and federal initiatives examining the use of alternative fuels for motor vehicles. Texas' program for alternate fuels includes compressed natural gas (CNG). Based on an analysis of 30-year life-cycle costs, development of a natural gas vehicle (NGV) program for the Texas Department of Transportation (TxDOT) would cost about $47 million (in 1991 dollars). These costs include savings from lower priced natural gas, infrastructure costs for a fast-fueling station, vehicle costs, and operating costs. The 30-year life-cycle costs translate into an average annual vehicle cost increase of $596, or about 4.9 cents more per vehicle mile of travel. Based on the cost-effectiveness analysis and assumptions, there are currently no TxDOT stations suitable for conversion to compressed natural gas NTIS

ADVANCED BRISTLE SEALS FOR GAS TURBINE ENGINES Final Report, May - Nov. 1992
Jerry L. Cabe 28 Jan. 1993 45 p
(Contract DAAJ02-92-C-0008)
(AD-A261296; FR9201-01) Avail: CASI HC A03/MF A01

A seven month proof-of-concept program was conducted for an advanced bristle seal, called a bush seal, for use in gas turbine engines. This program was performed as a Small Business Innovation Research (SBIR) Phase 1 project. Bush seal specimen and a full ring bush seal were designed, evaluated, and manufactured for testing. An analytical study of the potential of the bush seal relative to a labyrinth seal was conducted. Static and dynamic testing of the bush seal was performed to determine the behavior of the bristles under pressurization and during contact with a rotating labyrinth tooth. Stable behavior of the bristle elements was observed during static pressurization of a full ring bush seal. The dynamic testing of various configurations of bush seal against a rotating labyrinth tooth showed minimal wear of the bristles relative to a conventional labyrinth seal. The development and application of the bush seal concept to gas turbine engines has the potential of improving the engine's performance while decreasing the degradation of the seal performance over time. Increased emphasis on energy efficiency and air quality has resulted in a number of state and federal initiatives examining the use of alternative fuels for motor vehicles. Texas instituted an alternative fuels program for public fleet operations beginning in the 1991-92 fiscal year. Life-cycle cost/benefit models for evaluating the economic implications of the action have been developed at the University of Texas at Austin Center for Transportation Research for both compressed natural gas (CNG) and propane. The report documents the various input data, calculations, and assumptions of the Propane Net Present Value (NPV) model. A similar report (number 983-1) documents the same for the CNG model. Input data with constant values across different fleets and locations are discussed first and include basic parameters for on-board storage capacity, vehicle conversion costs, equipment salvage values, etc. Variable input data, reflecting a given fleet size, composition, and location, include the number and types of vehicles, fuel consumption, etc. The next section presents the formulas for the internal model calculations. The final section discusses the basic assumptions underlying the model. NTIS

INTERNAL STRAIN ANALYSIS OF CERAMICS USING SCANNING LASER ACOUSTIC MICROSCOPY Final Report
Renee M. Kent Mar. 1993 144 p
(Contract NCC3-81; RTOP 510-01-50)
(NASA-CR-191118; E-7308; NAS 1.26:191118) Avail: CASI HC A07/MF A02

Quantitative studies of material behavior characteristics are essential for predicting the functionality of a material under its operating conditions. A nonintrusive methodology for measuring the in situ strain of small dimeter (to 11 microns) ceramic fibers under uniaxial tensile loading and the local internal strains of ceramics and ceramic composites under flexural loading is introduced. The strain measurements and experimentally observed mechanical behavior are analyzed in terms of the microstructural development and fracture behavior of each test specimen evaluated. Measurement and analysis of Nicalon silicon carbide (SiC) fiber (15 microns diameter) indicate that the mean elastic modulus of the individual fiber is 185.3 GPa. Deviations observed in the experimentally determined elastic modulus values between specimens were attributed to microstructural variations which occur during processing. Corresponding variations in the fracture surface morphology were also observed. The observed local mechanical behavior of a lithium alumino-silicate (LAS) glass ceramic, a LAS/SiC monofilament composite, and a calcium alumino-silicate (CAS)/SiC fully reinforced composite exhibits nonlinearities and apparent hysteresis due to the subcritical mechanical loading. Local hysteresis in the LAS matrices coincided with the occurrence of multiple fracture initiation sites, localized microcracking, and secondary cracking. The observed microcracking phenomenon was attributed to stress relaxation of residual stresses developed during processing, and local interaction of the crack front with the microstructure. The relaxation strain and stress predicted on apparent mechanical hysteresis effects were defined and correlated with the magnitude of the measured fracture stress for each specimen studied. This quantitative correlation indicated a repeatable measure of the stress at which matrix microcracking occurred for stress relief of each material system. Stress relaxation occurred prior to the onset of steady state cracking conditions. The relaxation stress occurred at 18.5 percent of the fracture stress in LAS and 11.0 percent of the yield stress in CAS/SiC. The relaxation stress ratio was dependent upon the dominant fracture mode of the LAS/SiC specimens. Relaxation stress ratios greater than 0.30 were observed for specimens which fractured due to shear at the fiber matrix interface; specimens which fracture due to tensile cracking had relaxation stress ratios less than 0.30. The stress relaxation ratio appeared to be a specific characteristic of the glass ceramic material. The measured stress relaxation for LAS indicated a measure of the inherent residual stresses in the material due to processing and suggested localized toughening mechanisms for brittle material structures. In this paper we have shown that aluminum skin samples corroded in the laboratory by an electrochemical process are similar to corrosion that occurs naturally. Incorporating the corroded skins into several sets of characterized aluminum/adhesive lap-splices with first and second layer corrosion defects, we have shown qualitative agreement in PP signal amplitude between a low frequency ultrasonic model and experiment. The model suggests, and the experimental evidence agrees, that the trailing signal PP amplitude of a low frequency tri-polar pulse can be used to discriminate metal thinning in the second layer due to corrosion. Further work is in progress to address the issues of frequency selection and errors caused by layer parameter approximation. DOE

NONDESTRUCTIVE EVALUATION OF FERRITE c-CORES Final Report
J. W. Ekis Nov. 1992 18 p
(Contract DE-AC04-76DP-00613)
(KCP-613-4677) Avail: CASI HC A03/MF A01

A set of ultrasonic references for the ferrite c-cores for a strong link safety component were designed and manufactured. Ten sets of references were made for both the primary and the secondary c-cores. One set of each will be used to inspect loose piece parts. Second sets of each were mounted into transformer subassemblies. Third sets of each were mounted into transformers and welded into housing assemblies. These sets will be used to inspect their corresponding assemblies. All of these reference units were characterized using an ultrasonic test inspection system and calibrated by metrology. These reference units are now ready for use in product inspection. Author

Failure detectors (or, more accurately Failure Suspectors (FS)) appear to be a fundamental service upon which to build fault-tolerant, distributed applications. This paper shows that a FS with very weak semantics (i.e., that delivers failure and recovery information in no specific order) suffices to implement virtually-synchronous communication (VSC) in an asynchronous system subject to process crash failures and network partitions. The VSC paradigm is particularly useful in asynchronous systems and greatly simplifies building fault-tolerant applications that mask failures by replicating processes. We suggest a three-component architecture to implement virtually-synchronous communication: (1) at the lowest level, the FS component; (2) on top of it, a component (2a) that defines new views; and (3) a component (2b) that reliably multicasts messages within a view. The issues covered in this paper also lead to a better understanding of the various membership service semantics proposed in recent literature. Author (revised)

AUTOMATED INSPECTION OF SOLDER JOINTS FOR SURFACE MOUNT TECHNOLOGY

Robert M. Savage, Hyun Soo Park (Paramax Systems Corp., Lanham, MD.), and Mark S. Fan (Paramax Systems Corp., Lanham, MD.) Washington Mar. 1993 32 p Sponsored by NASA. Washington (RTOP 310-39-09-01-25)
(NASA-TM-104580; NAS 1.15:104580; Rept-93B00035) Avail: CASI HC A03/MF A01

Researchers at NASA/GSFC evaluated various automated inspection systems (AIS) technologies using test boards with known defects in surface mount solder joints. These boards were complex and included almost every type of surface mount device typical of critical assemblies used for space flight applications: X-ray radiography; X-ray laminography; Ultrasonic Imaging; Optical Imaging; Laser Imaging; and Infrared Inspection. Vendors, representative of the different technologies, inspected the test boards with their particular machine. The results of the evaluation showed limitations of AIS. Furthermore, none of the AIS technologies evaluated proved to meet all of the inspection criteria for use in high-reliability applications. It was found that certain inspection systems could supplement but not replace manual inspection for low-volume, high-reliability, surface mount solder joints. Author (revised)

EXPLORING THE LINK BETWEEN INTRINSIC MOTIVATION AND QUALITY M.S. Thesis
Steven M. Christy Dec. 1992 80 p
(AD-A261722) Avail: CASI HC A05/MF A01

This thesis proposes that it is workers' intrinsic motivation that leads them to produce quality work. It reviews two different types of evidence-expert opinion and empirical studies--to attempt to evaluate a link between intrinsic motivation and work quality. The thesis reviews the works of Total Quality writers and behavioral scientists for any connection they might have made between intrinsic motivation and quality. The thesis then looks at the works of Deming and his followers in an attempt to establish a match between Deming's motivational assumptions and the four task rewards in the Thomas/Tymon model of intrinsic motivation: choice, competence, meaningfulness, and progress. Based upon this analysis, it is proposed that the four Thomas/Tymon task rewards are a promising theoretical foundation for explaining the motivational basis of quality for workers in Total Quality organizations. (Grant AF-AFOSR-0360-91)
(AD-A261370) Avail: CASI HC A02/MF A01

The PI collaborated with Prof. Michael Vogelius on several problems. The research resulted in several reports, some of which have already been accepted for publication. The main research proposed was to investigate various aspects of the problem of electrical impedance tomography. In electrical impedance tomography, the problem is to image the interior of an object from static electrical measurements conducted on the boundary. The techniques of electrical impedance tomography may be applied to nondestructive evaluation of structures. The grant was directly responsible for two major accomplishments - (1) Inversion from real data and (2) Sensitivity of electrical impedance tomography. DTIC

(AD-A261786; WL-TR-92-4032) Avail: CASI HC A04/MF A01

Computed tomography (CT) has been used to evaluate specific sand casting product examples for technical and economic benefits. The representative results are applicable to other casting technologies as well. CT has been shown to be cost effective in the development of new castings. The areas which would benefit include internal dimensional measurements (eliminating destructive sectioning), specific region inspections, flaw characterization in critical regions (to allow passing or informed repair of castings), and geometric acquisition for CAD/CAM. The quantitative capability of CT allows an engineering evaluation of castings based upon a correlation with performance. This quantitative measurement capability has also been used to measure the benefit of hot isostatic pressing in casting production. CT is also cost effective for engineering design and analysis by providing rapid geometry acquisition for input to computer aided design systems. This is particularly beneficial for components that do not have existing drawings or cannot be adequately defined until they are made for any reason. Presently CT can serve as an engineering aid to casting manufacturing. In order for CT evaluation to become routine in foundry applications, however, casting designers need to call it out as a measurement technique in the original casting design drawings, specifications on the application of CT must be written, contracts must include CT evaluation as a means for accepting casting quality, and lower cost CT systems must be available. DTIC

X RAY COMPUTED TOMOGRAPHY FOR FAILURE ANALYSIS Interim Report, May 1991 - Jan. 1992
Richard H. Bossi, Alan R. Crews, and Gary E. Georgeson 31 Aug. 1992 56 p
(Contract F33615-88-C-5404)
(AD-A261884; WL-TR-91-4102) Avail: CASI HC A04/MF A01

Under a preliminary testing task assignment of the Advanced Development of X-Ray Computed Tomography Application program, computed tomography (CT) has been studied for its potential as a tool to assist in failure analysis investigations. CT provides three-dimensional spatial distribution of material that can be used to assess internal configurations and material conditions nondestructively. This capability has been used in failure analysis studies to determine the position of internal components and their operation. CT is particularly advantageous on complex systems, composite failure studies, and testing under operational or environmental conditions. CT plays an important role in reducing the time and effort of a failure analysis investigation. Aircraft manufacturing or logistical facilities perform failure analysis operations routinely and could be expected to reduce schedules, reduce costs and/or improve evaluation on about 10 to 30 percent of the problems they investigate by using CT. VIBRATION, BUCKLING, AND POSTBUCKLING OF LAMINATED COMPOSITES WITH DELAMINATIONS Ph.D. Thesis
Jaehong Lee 1992 234 p
Avail: Univ. Microfilms Order No. DA9229606

Free vibration, buckling, and postbuckling analyses of laminated composite plates with multiple delaminations are presented. A finite element method based on a layer-wise laminated composite plate theory is developed to formulate the problem. Geometric nonlinearity in the sense of von Karman and the imperfection in the plate in the form of initial global deflection and initial delamination openings are included. A simple contact algorithm which precludes the physically inadmissible overlapping between delaminated surfaces is proposed and incorporated in the analysis. A sublaminate concept is adopted in the analysis to reduce the computational efforts. The concept was found to be efficient. Numerical results are obtained for through-the-width, circular and rectangular delaminations addressing the effects of the number of delaminations, their lengths and through-the-thickness and axial locations on the critical buckling load, and buckling mode shapes as well as free vibration frequency and modes. Postbuckling responses are investigated with respect to different magnitudes and directions of initial imperfections. The effects of material anisotropy and contact condition between delaminated surfaces are also considered. It is found that the proposed approach is very efficient and powerful for solving the above mentioned problems. Dissert. Abstr.

EVALUATION OF MARC FOR THE ANALYSIS OF ROTATING COMPOSITE BLADES
Karen F. Bartos and Michael A. Ernst Washington Mar. 1993 27 p
(RTOP 535-03-10)
(NASA-TM-4423; E-7163; NAS 1.15:4423) Avail: CASI HC A03/MF A01

The suitability of the MARC code for the analysis of rotating composite blades was evaluated using a four-task process. A nonlinear displacement analysis and subsequent eigenvalue analysis were performed on a rotating spring mass system to ensure that displacement-dependent centrifugal forces were accounted for in the eigenvalue analysis. Normal modes analyses were conducted on isotropic plates with various degrees of twist to evaluate MARC's ability to handle blade twist. Normal modes analyses were conducted on flat composite plates to validate the newly developed coupled COBSTRAN-MARC methodology. Finally, normal modes analyses were conducted on four composite propfan blades that were designed, analyzed, and fabricated at NASA Lewis Research Center. Results were compared with experimental data. The research documented herein presents MARC as a viable tool for the analysis of rotating composite blades. Author

AXISYMMETRIC DEFORMATIONS AND STRESSES OF UNSYMMETRICALLY LAMINATED COMPOSITE CYLINDERS IN AXIAL COMPRESSION WITH THERMALLY-INDUCED PRELOADING EFFECTS
Peter J. Paraska Mar. 1993 183 p
(Grant NAG1-901)
(NASA-CR-192788; NAS 1.26:192788; CARDEROCKDIV-U-SSM-65-93/03)
Avail: CASI HC A09/MF A02

This report documents an analytical study of the response of unsymmetrically laminated cylinders subjected to thermally-induced preloading effects and compressive axial load. Closed-form solutions are obtained for the displacements and intralaminar stresses and recursive relations for the interlaminar shear stress were obtained using the closed-form intralaminar stress solutions. For the cylinder geometries and stacking sequence examples analyzed, several important and as yet undocumented effects of including thermally-induced preloading in the analysis are observed. It should be noted that this work is easily extended to include uniform internal and/or external pressure loadings and the application of strain and stress failure theories. Derived from text

HIGH TEMPERATURE COMPOSITE ANALYZER (HITCAN) THEORETICAL MANUAL, VERSION 1.0
J. J. Lackney (Sverdrup Technology, Inc., Brook Park, OH.), P. L. N. Murthy, and P. K. Gotsis Apr. 1993 58 p
(Contract NAS3-25266; RTOP 505-63-5B)
(NASA-TM-106001; E-7544; NAS 1.15:106001) Avail: CASI HC A04/MF A01

This manual outlines some of the theoretical aspects embedded in the computer code, HITCAN (High Temperature Composite ANalyzer). HITCAN is a general purpose computer program for predicting nonlinear global structural and local stress-strain response of arbitrarily oriented, multilayered high temperature metal matrix composite structures. This code combines composite mechanics and laminate theory with an internal data base of the constituents (matrix, fiber and interface) material properties. The thermal and mechanical properties of the constituents are considered to be nonlinearly dependent on several parameters including temperature, stress and stress rate. The computational procedure for the analysis of the composite structure uses the finite element method. HITCAN consists of three modules: COBSTRAN, METCAN and MHOST. COBSTRAN generates the geometry (pre-processor) and defines the layup of the different plies. METCAN computes the material behavior of the composite and of the constituents. Finally, MHOST is a finite element program based on the mixed iterative solution technique. MHOST has a library for 2D and 3D isoparametric elements. HITCAN is written in FORTRAN 77 computer language and has been configured and executed on the NASA Lewis Research Center CRAY XMP and YMP computers. Author

SEISMIC BUCKLING CAPACITY OF UNSTIFFENED, FREE-STANDING STEEL CONTAINMENTS
Charles R. Farrar, Thomas A. Duffey, Peggy A. Goldman, and Joel G. Bennett Jul. 1992 150 p
(Contract W-7405-eng-36)
(DE93-005325; LA-12359-MS) Avail: CASI (US Sales Only)

An investigation of the seismic buckling capacity of two unstiffened, freestanding steel containments is reported. The first structure studied is a proposed next-generation containment whose geometry is driven by the need for a passive cooling mechanism. For the second structure, a survey of commercial nuclear reactor containments was used to develop a generic design indicative of existing unstiffened, free-standing containments. This generic structure is also assumed to be indicative of a smaller scale version of the next-generation, passively cooled containments. A simple

three-degree-of-freedom (3-DOF), axisymmetric model of the containments is analyzed using response spectrum methods to determine the zero-period acceleration that would produce a case of incipient buckling. Then, more refined numerical time-history analyses were performed using the ABAQUS finite element code. The numerical models were subjected to measured earthquake acceleration-time histories and to artificial earthquake acceleration-time histories whose response spectra matched the Reg. Guide 1.60 design spectra, an eastern U.S. site-specific design spectra, and a spectrum that includes soil-structure interaction effects. The effects of containment construction methods and the effects of the internal negative air pressure on containment buckling are examined. Additionally, applications of the work presented in this study to the development of a simplified margins assessment method are discussed. Finally, a summary of buckling concerns, which the authors feel have been inadequately addressed in Code Case N-284, is presented. In the conclusion, the level of safety of a proposed next-generation containment design for seismically induced buckling is compared with the level of safety of existing commercial nuclear power plant containments for this failure mode. HIGH TEMPERATURE COMPOSITE ANALYZER (HITCAN) USER'S MANUAL, VERSION 1.0

J. J. Lackney (Sverdrup Technology, Inc., Brook Park, OH.), S. N. Singhal (Sverdrup Technology, Inc., Brook Park, OH.), P. L. N. Murthy, and P. Gotsis Apr. 1993 180 p

(RTOP 505-63-5B)

(NASA-TM-106002; E-7545; NAS 1.15:106002) Avail: CASI HC A09/MF A02

This manual describes 'how-to-use' the computer code, HITCAN (HIgh Temperature Composite ANalyzer). HITCAN is a general purpose computer program for predicting nonlinear global structural and local stress-strain response of arbitrarily oriented, multilayered high temperature metal matrix composite structures. This code combines composite mechanics and laminate theory with an internal data base for material properties of the constituents (matrix, fiber and interphase). The thermo-mechanical properties of the constituents are considered to be nonlinearly dependent on several parameters including temperature, stress and stress rate. The computation procedure for the analysis of the composite structures uses the finite element method. HITCAN is written in FORTRAN 77 computer language and at present has been configured and executed on the NASA Lewis Research Center CRAY XMP and YMP computers. This manual describes HITCAN's capabilities and limitations followed by input/execution/output descriptions and example problems. The input is described in detail including (1) geometry modeling, (2) types of finite elements, (3) types of analysis, (4) material data, (5) types of loading, (6) boundary conditions, (7) output control, (8) program options, and (9) data bank. HYPERVELOCITY IMPACT STUDY: THE EFFECT OF IMPACT ANGLE ON CRATER MORPHOLOGY Interim Report

Gary Crawford, David Hill, Frank E. Rose, Ralph Zee, Steve Best, and Mike Crumpler 15 Mar. 1993 11 p

(Grant NAG1-1329)

(NASA-CR-192711; NAS 1.26:192711) Avail: CASI HC A03/MF A01

The Space Power Institute (SPI) of Auburn University has conducted preliminary tests on the effects of impact angle on crater morphology for hypervelocity impacts. Copper target plates were set at angles of 30 deg and 60 deg from the particle flight path. For the 30 deg impact, the craters looked almost identical to earlier normal incidence impacts. The only difference found was in the apparent distribution of particle residue within the crater, and further research is needed to verify this. The 60 deg impacts showed marked differences in crater symmetry, crater lip shape, and particle residue distribution. Further research on angle effects is planned, because the particle velocities for these shots were relatively slow (7 km/s or less). Author (revised)

NONHOLONOMIC GEOMETRY, MECHANICS AND CONTROL Ph.D. Thesis

Rui Yang 1992 174 p

Avail: Univ. Microfilms Order No. DA9304413

This dissertation is concerned with dynamic modeling and kinematic control of constrained mechanical systems with symmetry from a geometric point of view. Constraints are defined via the characteristics of distributions or codistributions on the tangent bundle (velocity phase space) of configuration space. Lie symmetry groups acting on the systems are assumed to leave both Lagrangian and constraints invariant. As a special case of mechanical systems with holonomic constraints, we rigorously analyze the kinematics and dynamics of floating, planar four-bar linkages. The analyses include a topological description of the configuration space, symplectic and Poisson reductions of the dynamics, and bifurcation of relative equilibria. For kinematic control of nonholonomic systems, we mainly study the related optimal control problem for a system consisting of a rigid body with two oscillators. In particular, the intrinsic formulation and explicit solvability of necessary conditions for the optimal control are investigated from a Hamiltonian point of view. In the study of the dynamics of Lagrangian systems with constraints, the nonholonomic distributions are defined via arbitrary choices of principal connections. We show that, under our hypotheses on constraints and exterior force, the dynamics of a nonholonomic Lagrangian system with non-Abelian symmetry can be reduced to a lower dimensional space determined by the principal fiber bundle. The reduced dynamic equations are formulated explicitly. This formulation generalizes the one for classical Chaplygin systems which possess Abelian symmetry and the one having non-Abelian symmetry but with linear constraints. In addition, if a special principal connection, that is, the mechanical connection by Kummer and Smale, is considered, our formulation for nonholonomic systems also leads to the one in Lagrangian reduction discovered recently by Marsden and Scheurle. The results of this dissertation have direct application in space robotics and nonholonomic motion planning in robotics. Dissert. Abstr.

EQUILIBRIUM CONSTRAINED ASSUMED NATURAL COORDINATE STRAIN FINITE ELEMENTS FOR SHELL ANALYSIS Ph.D. Thesis

Daniel Duane Jensen 1992 229 p

Avail: Univ. Microfilms Order No. DA9304569

Substantial enhancements have been made in the Assumed Natural-coordinate Strain (ANS) finite elements leading to a new class of plate and shell finite elements entitled Equilibrium Constrained Assumed Natural-coordinate Strain (ANS-EC). Hierarchical degrees of freedom (dof) augment the standard dof in these new elements. These hierarchical dof are then eliminated using 'kinematic' and 'strong form equilibrium' constraints at selected discrete points. Kinematic constraints are used to reduce the polynomial order of the transverse shear strains. Equilibrium based constraints enforce the strong form of both the 'moment-transverse shear' equilibrium and the 'membrane resultant-transverse shear' equilibrium at discrete locations in each element. This combination of constraints causes the elements to avoid shear locking in the thin limit. The elements are fully integrated, which eliminates spurious mechanisms. As with all of the ANS elements, a full tensor transformation replaces the Jacobian transformation used in isoparametric formulations resulting in reduced distortion sensitivity. These element modifications are completely contained in the strain-displacement matrix. This formulation produces a modified shape function matrix for use in creating consistent nodal loads. The result is a set of elements which has substantial improvements in stress accuracy as well as improved displacement convergence. Dissert. Abstr.

ON THE EFFECTIVE REFLECTION PROPERTIES OF THE RANDOMLY SEGMENTED ELASTIC BAR

Zbigniew Kotulski 1992 44 p Sponsored by Komitet Badan Naukowych

Avail: CASI HC A03/MF A01

In the paper transition of the wave pulses through bars with random properties is investigated. It is assumed that the bar is built of several homogeneous segments. It is permitted that the lengths of the segments as well as their material parameters are random variables. The overall properties of such bars are studied. The discussion of obtained results is illustrated with numerical calculations. Author

THREE-DIMENSIONAL BOUNDARY ELEMENT ANALYSIS OF CONTACT AND FRACTURE PROBLEMS Ph.D. Thesis
Minzhu Liu 1992 138 p
Avail: Univ. Microfilms Order No. DA9301341

A general purpose three dimensional boundary element method is developed for elastic solids. Emphasis is placed on the unique requirements of contact and fracture problems. In order to allow efficient and detailed calculations near the region of contact, special infinite elements that include the exact effects of infinite boundaries are developed. It is shown that these infinite elements can be used to accurately calculate contact stresses with very few elements. The effect of naturally occurring three dimensional defects on stresses and fatigue life is calculated. A void reduces the maximum allowable fatigue limit design pressure by 75 percent while a hard inclusion reduces it by 25 percent. The modified crack closure integral is used to accurately calculate the three-dimensional stress intensity factors. A multidomain approach is utilized for mixed mode cracks. In general the error of prediction of the stress intensity factors is within +/- 1.5 percent. Finally, the sliding blister field model of sliding micro indentation fracture is shown to give qualitative agreement with experimentally observed crack growth. Dissert. Abstr.

DETAILED SOLUTION TO A COMPLEX KINEMATICS CHAIN MANIPULATOR
S. March-Leuba, J. F. Jansen, R. L. Kress, and S. M. Babcock 1992 10 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-004619; CONF-930519-6) Avail: CASI HC A02/MF A01

A relatively simple method based on planar geometry to analyze the inverse kinematics for closed kinematics chain (CKC) mechanisms is presented. Although the general problem and method of approach are well defined, the study of the inverse kinematics of a closed-chain mechanism is a very complicated one. The current methodology allows closed-form solutions to be found, if a solution exists, for the displacements and velocities of all manipulator joints. Critical design parameters can be identified and optimized by using symbolic models. Focus is on planar closed-chain structures extended with a rotational base. However, with open and CKC mechanisms combined in different planes, the extension to the case is straightforward. Further, real-time algorithms are developed that can be handled by existing microprocessor technology. To clarify the methodology, the Soldier Robot Interface Project (SRIP) manipulator is analyzed, and a graphic simulation is presented as a verification of the results. This manipulator has 17 links, 24 one-degree-of-freedom (DOF) joints, and 7 CKC loops working in a plane and a rotational base, which determine its 3 DOF's. The SRIP manipulator allows a decoupled linear motion along the vertical or horizontal directions using only one of its linear actuators. The symbolic solution for the inverse kinematics allows optimization to be performed to further decouple the Cartesian motions by changing link lengths of the manipulator. The conclusion achieved by the optimization is that only two link lengths need to be changed to tune the manipulator for a perfect decoupling at each area of the workspace. DOE

ANALYSIS OF PULL-TESTS FOR DETERMINING THE EFFECTS OF ION IMPLANTATION ON THE ADHESION OF IRON FILMS TO SAPPHIRE SUBSTRATES
J. E. Pawel and C. J. McHargue (Tennessee Univ., Knoxville.) 1992 19 p Presented at the International Symposium on Adhesion Measurement of Films and Coatings, Cambridge, MA, 5-7 Dec. 1992
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE93-006732; CONF-921257-1) Avail: CASI HC A03/MF A01

Various chemical species were implanted at the interface between evaporated iron films and their sapphire substrates. From interfacial free energy considerations, it was postulated that implantation of Cr ions should increase the strength of the bond between iron. and sapphire, whereas implantation of Ni ions should weaken the bonds. Implantation of Fe ions should cause changes due to irradiation-produced defects but exhibit no chemical effect. The pull test was used to evaluate the bond strength of unimplanted and implanted specimens. Since there was large scatter in the data, it was necessary to conduct a statistical analysis. It was assumed that the separation of the film from the substrate was nucleated by interfacial defects in the bond. Because the Weibull analysis was developed to describe the failure probability due to a population of flaw-induced cracks, this technique was used to interpret the data. DOE

NUMERICALLY DISSIPATIVE TIME INTEGRATION ALGORITHMS FOR STRUCTURAL DYNAMICS Ph.D. Thesis
Jintai Chung 1992 129 p
Avail: Univ. Microfilms Order No. DA9303717

New dissipative time integration algorithms are presented for solving systems of second-order ordinary differential equations that typically arise from the spatial discretization of elastodynamics problems. The new algorithms are: (1) a family of implicit generalized-alpha methods, (2) a family of explicit generalized-alpha methods, and (3) a family of single step Houbolt methods (implicit and implicit/explicit). Analyses of the algorithms are carried out systematically with particular emphasis on numerical dissipation, accuracy and stability. The implicit generalized-alpha method possesses numerical dissipation that can be controlled by the user. In particular, it is shown that the generalized-alpha method achieves high-frequency dissipation while minimizing unwanted low-frequency dissipation. Comparisons are given of the generalized-alpha method with other numerically dissipative methods; these results highlight the improved performance of the new algorithm. The new algorithm can be easily implemented into programs that include standard time integration methods. The explicit generalized-alpha method possesses controllable high-frequency algorithmic damping; moreover, in the presence of physical damping, the algorithm simultaneously maintains a truly explicit form and second-order accuracy. A numerical example is given to compare the proposed method with the central difference method; the result demonstrates the effectiveness of the new method. The implicit single-step Houbolt method is unconditionally stable, second-order accurate and asymptotically annihilating. It is spectrally equivalent to Houbolt's method but is cast in the more convenient single-step form rather than multi-step form. An explicit predictor-corrector algorithm based upon the new implicit scheme is spectrally equivalent to the central difference method. The two algorithms are merged into an implicit-explicit method, resulting in an improved algorithm for solving structural dynamics problems composed of 'soft' and 'stiff' domains. Dissert. Abstr.

NUMERICAL INVESTIGATIONS ON FRACTURE BEHAVIOR OF DUCTILE MATERIALS Ph.D. Thesis
Tung-Li Weng 1992 227 p
Avail: Univ. Microfilms Order No. DA9301407

The objective of the present work was to establish a criterion to characterize the fracture behavior of crack extension in ductile materials. The first part of this dissertation explored some useful techniques dealing with the fracture behavior of nonlinear elastic solid as the ideal model for ductile material. Five different methods of calculation of non-linear strain energy release rates were investigated. Their efficiencies and accuracies were compared and discussed. The present work identified the cause of deviations between the numerical result and the HRR solution. The present result showed that all field components near the crack tip converged to the HRR solutions in all directions if FEM meshes were sufficiently refined, and that the HRR fields exist not only for small scale yielding, but also for general yielding. Moreover, the near tip field solutions for incremental plasticity are almost identical to those for deformation plasticity. For incremental plasticity, however, the crack tip fields progressively deviate from the HRR solutions as elastic unloading occurs. The present work also investigated the plastic crack tip fields in the presence of residual stresses. To establish a ductile fracture criterion, several potential fracture parameters were investigated in simulations of crack extensions by combining numerical techniques with existing experimental results. Based on the present observations, a fracture criterion, the Global-Local Fracture Criterion (GLFC) was proposed. The feasibility of the proposed fracture criterion in predicting the ductile fracture behavior was extensively verified. It was shown that the GLFC is highly accurate and is satisfactory for ductile fracture analyses. Dissert. Abstr.

FATIGUE RESISTANCE OF ORTHOTROPIC PLATES WITH TRAPEZOIDAL STIFFENERS
J. Thonnard and J. Janss Aug. 1985 39 p
(TRL-Trans-T3908; MT-161) Avail: CASI HC A03/MF A01

The use of trapezoidal-shaped, continuous, closed stiffeners, in the construction of metal bridges with orthotropic plates has increased considerably. The welded joints between stiffeners and the floor plate must be designed and made in such a way as to prevent any risk of fatigue failure when in service. This is why the Ministry of Public Works, the main user of orthotropic plates in Belgium, imposes a certain number of requirements for the construction of such plates. However, these requirements are costly, and one wonders whether they are really indispensable, given the usual dimensions of trapezoidal stiffeners and the real stresses imposed on bridges. The behavior of welded joints between closed stiffeners (6 mm thick) and floor plate (12 mm thick) under dynamic loadings is studied. The welds were made according to less strict requirements than is usual in Belgium. The tests showed that the range of fluctuations of transverse stresses sigma in the stiffener, at the root of the weld beads, which equals 80 N/mm(sup 2), may be considered the endurance limit, if the lack of union between plate and stiffener is 0.5 mm or less, the lack of penetration of the weld is in the region of 4 mm and the edges of the stiffeners have not been specially prepared.

STOCHASTIC AND SEISMIC DESIGN RESPONSE OF LINEAR AND NONLINEAR STRUCTURES Ph.D. Thesis
Gustavo Omar Maldonado 1992 288 p
Avail: Univ. Microfilms Order No. DA9302671

New methods for calculating the stochastic and seismic design response of linear and nonlinear structures are presented. For linear structures, two approaches are developed: (1) the modified mode displacement approach for classically as well as non-classically damped structures; and (2) the generalized force derivative approach for classically damped structures. Both techniques improve the calculation of the pseudostatic contribution of the truncated modes without including them in the analysis. In particular, the modified mode displacement approach is a useful tool for the calculation of seismic design responses affected by the contributions of higher modes. It properly considers the modal correlations as well as the correlation between retained and truncated modes. It is as fast as the mode acceleration method of structural dynamics and it only requires the commonly used ground response spectra employed by the classical mode displacement approach. On the other hand, the generalized force derivative approach requires the input to be defined in terms of its power spectral density function, but it improves even further the estimation of the missing mass effect due to the truncation of modes. For nonlinear structures, the stochastic equivalent linearization technique is employed to develop response spectrum approaches for hysteretic shear buildings and for two dimensional frames with plastic hinges. For this purpose, a generalized modal analysis technique is successfully employed. The proposed response spectrum approaches require the input be defined in terms of the response spectrum of first order oscillators as well as in terms of the commonly used ground response spectra. For shear buildings, the work is extended to include the calculation of floor response spectra. A simulation study is performed to compare the results obtained by the proposed approach.

PYROSHOCK: BIBLIOGRAPHY
R. M. Zimmerman 1993 8 p The 39th Annual Technical Meeting of the Institute of Environmental Sciences, held in Las Vegas, NV, 2-7 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-007605; SAND-93-0331C; CONF-930529-1) Avail: CASI HC A02/MF A01

This paper represents a review copy for text that is to be included in the Shock and Vibration Recommended Practice Document. This section on pyroshock is written as a general introduction to and description of the topic leading to presentation of an extensive bibliography on the subject. Pyroshock is an evolving science that needs continued focus on both achieving improvements in testing and measurement techniques and advancing instrumentation capabilities. Pyroshock phenomena are associated with separation systems of missiles, spacecraft, and in some cases airplanes. During launch, a rocket driven vehicle may be exposed to 19 to 30 g's of acceleration with predominant frequencies less than 200 Hz. After launch or takeoff, sections or parts of vehicles may be separated rapidly using explosive driven release mechanisms. Separations can involve stage disconnections for spacecraft sections or payload ejections from missiles and airplanes. At separation, localized pyrotechnic induced accelerations may range from 1000 to over 100,000 g's at frequencies much higher than 1000 Hz. These pyroshocks are characterized by high intensity, high frequency transients that decay rapidly. Pyroshock impulses have insignificant velocity changes.

STRESS AND RELIABILITY ANALYSES OF MULTILAYERED COMPOSITE CYLINDER UNDER THERMAL AND MECHANICAL LOADS Ph.D. Thesis
Xiaohua Wang 1992 217 p
Avail: Univ. Microfilms Order No. DA9306161

The coupling resulting from the mutual influence of material thermal and mechanical parameters is examined in the thermal stress analysis of a multilayered isotropic composite cylinder subjected to sudden axisymmetric external and internal temperature. The method of complex frequency response functions together with the Fourier transform technique is utilized. Because the coupling parameters for some composite materials, such as carbon-carbon, are very small, the effect of coupling is neglected in the orthotropic thermal stress analysis. The stress distributions in multilayered orthotropic cylinders subjected to sudden axisymmetric temperature loading combined with dynamic pressure as well as asymmetric temperature loading are also obtained. The method of Fourier series together with the Laplace transform is utilized in solving the heat conduction equation and thermal stress analysis. For brittle materials, like carbon-carbon composites, the strength variability is represented by two or three parameter Weibull distributions. The 'weakest link' principle which takes into account both the carbon-carbon composite cylinders. The complex frequency response analysis is performed on a multilayered orthotropic cylinder under asymmetrical thermal load. Both deterministic and random thermal stress and reliability analyses can be based on the results of this frequency response analysis. The stress and displacement distributions and reliability of rocket motors under static or dynamic line loads are analyzed by an elasticity approach. Rocket motors are modeled as long hollow multilayered cylinders with an air core, a thick isotropic propellant inner layer and a thin orthotropic kevlar-epoxy case. The case is treated as a single orthotropic layer or a ten layered orthotropic structure. Five material properties and the load are treated as random variable with normal distributions when the reliability of the rocket motor is analyzed by the first-order, second-moment method (FOSM).

RELIABLE STRESS AND FRACTURE MECHANICS ANALYSIS OF COMPLEX AIRCRAFT COMPONENTS USING A h-p VERSION OF FEM
Borje Andersson, Ivo Babuska, Tobias VonPetersdorff, and Urban Falk Aug. 1992 51 p
(Contract N00014-90-J-1030)
(AD-A260628; FFA-TN-1992-17) Avail: CASI HC A04/MF A01

Effective approaches are developed with which complex three-dimensional components may be analyzed with a high and virtually guaranteed accuracy. The main computational tool is a h-p version of

FEM practically realized with the p-version program STRIPE having a mesh generator for automatic mesh refinement at edges and vertices. Use of advanced extraction methods and new theoretical approaches give exponential convergence rates for accuracies in all engineering data of interest. New methods for reliable calculation of local stresses and stress intensity data at edges and vertices to be used for fatigue dimensioning at fillets, damage tolerance assessment of three-dimensional flaws etc. are given. A complex real-life problem is reliably analyzed in order to demonstrate the practical usefulness of the procedures advocated. The technical details are given in forthcoming papers. DTIC

CONTINUUM AND MICROMECHANICS TREATMENT OF CONSTRAINT IN FRACTURE Final Report
R. H. Dodds, Jr., C. F. Shih, and Ted L. Anderson Jan. 1993 46 p
(Contracts N00167-92-K-0038; N61533-92-R-0030)
(AD-A260927; UILU-ENG-92-2014; CDNSWC/SME-19-92) Avail: CASI HC A03/MF A01

This report explores the fundamental concepts of the J-Q description of crack-tip fields, the fracture toughness locus, and micromechanics approaches to predict the variability of macroscopic fracture toughness with constraint under elastic-plastic conditions. While these concepts are derived from plane-strain considerations, initial applications in fully 3D geometries are very promising. Computational results are presented for a surface cracked plate containing a 6:1 semi-elliptical, alpha = t/4 flaw subjected to remote uniaxial and biaxial tension. Crack-tip stress fields consistent with the J-Q theory are demonstrated to exist at each location along the crack front. The micromechanics model employs the J-Q description of crack-front stress to interpret fracture toughness values measured on laboratory specimens for fracture assessment of the surface cracked plate. The computational results suggest only a minor effect of the biaxial loading on the crack tip stress fields and, consequently, on the propensity for fracture relative to the uniaxial loading. DTIC

THERMOELASTIC STRESSES IN MULTI-LAYERED MEDIA IN NON-UNIFORM TEMPERATURE FIELDS Final Report, Jan. - Dec. 1992
David Salinas, Young W. Kwon, and Michael J. Neibert 31 Dec. 1992 43 p
(AD-A260901; NPS-ME-92-005) Avail: CASI HC A03/MF A01

The objective of this investigation is to determine the shear and peeling stresses in a multilayered media in a nonuniform temperature field. The temperature field is obtained by a finite element solution of the energy equation with a flux generation term in one of the media layers. The resulting thermoelastic stresses are then obtained from a finite element mode which uses a recently developed beam element with only displacement degrees of freedom. Compared to the standard beam element with rotational degrees of freedom, this element without rotational degrees of freedom more readily provides displacement continuity along interfaces between medial layers. As a result of the differences in properties such as Young's moduli, Poisson's ratio, and coefficients of thermal expansion, thermoelastic stresses develop when the multilayered media is subjected to a thermal environment. AN EFFICIENT TECHNIQUE FOR STRUCTURAL RELIABILITY WITH APPLICATIONS Ph.D. Thesis
Ibrahim Mustafa Janajreh 1992 200 p
Avail: Univ. Microfilms Order No. DA9306158

An efficient reliability technique has been developed based on Response Surface Methodology (RSM) in conjunction with the First Order Second Moment (FOSM) reliability method. The technique is applied when the limit state function cannot be obtained explicitly in terms of the design variables, i.e., when the analysis is performed using numerical techniques such as finite elements. The technique has proven to be efficient because it can handle problems with large numbers of design variables and correlated as well as nonnormal random variables. When compared with analytical results, the method has shown excellent agreement. The technique contains a sensitivity analysis scheme which can be used to reduce the computation time resulting in nearly the same accuracy. This technique allows the extension of most finite element codes to account for probabilistic analysis, where statistical variations can be added to the design variables. An explicit solution for rocket motors consisting of propellant and steel case under environmental temperature variations is compared to the RSM technique. The method is then used for the analysis of rocket motors subjected to mechanical loads for which the stress analysis is performed using the finite element method. The technique is also applied to study the reliability of a laminated composite plate with geometric nonlinearity subjected to static and time dependent loadings. Different failure modes were considered as well as different meshes. Results have shown that when the relative size of the element is introduced into the probabilistic model, the same reliability value is obtained regardless of the number of elements in the mesh. This is good because it allows the technique to be used for problems where the failure region is unknown. Dissert. Abstr.

PASSIVE VIBRATION DAMPING MATERIALS: PIEZOELECTRIC CERAMICS COMPOSITES FOR VIBRATION DAMPING APPLICATIONS Annual Technical Report, 1 Jan. 1992 - 31 Jan. 1993
Shoko Yoshikawa and S. K. Kurtz 11 Feb. 1993 24 p
(Contract N00014-92-J-1391)
(AD-A260792) Avail: CASI HC A03/MF A01

For application of the shunted passive piezoelectric damping of structural composites, piezoelectric ceramic fibers (PZT and its family) of several tens of micron diameter were made using sol-gel spinning process. Both acetate and acetylacetonate processes were examined as lead sources. Using the properly chosen spinneret and fiber drawing apparatus, PZT and modified PZT fibers of 10 to 100 micrometers diameter have been successfully produced. Different heat treatments gave different microstructure. Modeling analysis was also performed to estimate achievable damping levels for the composites. The results indicate high damping potential for shunted piezoelectric passive damping composites. DTIC

DEVELOPMENT AND APPLICATION OF AN ADVANCED DUCTILE FRACTURE MECHANICS METHODOLOGY Ph.D. Thesis
Zhen Zhou 1992 317 p
Avail: Univ. Microfilms Order No. DA9233603

An advanced ductile fracture mechanics methodology is presented here. This methodology takes a load versus displacement result from a laboratory specimen test to predict the load versus displacement for a structural component containing crack-like defect. To use this methodology, three steps need to be followed. First a test record from laboratory experiment needs to be reduced into two pieces of information, the calibration function and the fracture toughness. The calibration function relates load, displacement and crack size. The fracture toughness relates crack driving force and crack extension in terms of a J-R curve. The second step is to transfer this information to a structural component to be analyzed. After the calibration function and the fracture toughness for the structural component are determined, the last step is to use a ductile fracture methodology proposed by Ernst and Landes to predict the load versus displacement behavior of the structural component. Traditionally the J-R curve has been developed according to the ASTM standard. Crack growth is usually estimated by instrumentation. This does not always work well for non-side grooved specimens and polymeric materials. To ensure accurate data reduction, the normalization method for J-R curve calculation is further developed by introducing the LMN function as the calibration function. The new version of the normalization method works well for both metallic and polymeric materials. It is more reliable and versatile than the compliance method. Two procedures for the determination of the LMN function are introduced. Two procedures are developed for generating the calibration function for a structural component of interest. One is the transformation procedure that can be applied to the case where the limit load solution for the structural component is known. The other procedure is based on numerical simulation incorporating with the load separation method. This procedure can be used to any structural component whose behavior can be represented by load versus displacement. The methodology has been used to predict the behavior of different structural components with various cracks. The predictions are compared with the experimental results for most cases. In general, the predictions are accurate and successful.

MODELS OF CRACK GROWTH ALONG POLYMER INTERFACES Ph.D. Thesis
Daben Xu 1992 176 p
Avail: Univ. Microfilms Order No. DA9236086

Several models of crack growth along polymer/polymer interfaces are investigated in this work. The core spirit of these models is the use of a cohesive zone to study the effect of rate dependent inelastic deformation and damage directly ahead of the tip of a growing crack at the polymer interfaces. For each interface model studied, the fracture toughness of the interface is predicted as a function of the crack growth rate, the interface constitutive behavior and the properties of bulk materials surrounding the interface. In chapter 1, we present a general formulation of cohesive zone models in an elastic medium. Asymptotic behavior at the two ends of the cohesive zone is derived. Detailed analyses are carried out for the special case of a crack growing along a power-law creeping interface under steady state condition. Asymptotic and numerical solutions in the cohesive zone for this model are obtained. In chapter 2, we study the problem of steady state crack growth along the interface of two immiscible homopolymers. The interface is strengthened by the addition of a small amount of diblock copolymer. A interface constitutive model based on the concept of polymer chain pull-out is proposed and the results of the analysis are compared with experimental results. In chapter 3 and chapter 4, we study the fracture behavior of weakly joined adhesives between two viscoelastic polymers. In this case, the energy dissipation due to viscoelastic deformation in the bulk materials outside the interface contributes significantly to the measured interface fracture toughness. The presence of viscoelastic deformation implies that the loading parameters governing the crack tip fields are in general dependent on the specimen dimensions as well as the crack growth rate. Therefore, analyses are carried out for both infinite and finite specimens. Our results are compared to some experimental observations. The dependence of the fracture toughness of the interface on the properties of adhesive and the viscoelastic bulk material are derived and discussed.

EXPLOITATION OF CYCLOSTATIONARITY FOR SIGNAL-PARAMETER ESTIMATION AND SYSTEM IDENTIFICATION Semiannual Report, 1 Jul. - 31 Dec. 1992
William A. Gardner and Stephan V. Schell 31 Dec. 1992 5 p
(Contract N00014-92-J-1218)
(AD-A260833) Avail: CASI HC A01/MF A01

The cyclostationarity property of communications and telemetry signals enables the generation of spectral lines with appropriate nonlinear transformations and renders fluctuations in distinct spectral bands statistically dependent. The frequencies at which spectral lines can be generated are directly related to the separations between dependent spectral bands, which in turn are directly related to carrier frequencies, keying rates, pulse rates, and so on, in the signal. These inherent properties of cyclostationary signals can be exploited to great advantage for numerous tasks in signal processing. The objectives of the research being conducted are to investigate new cyclostationarity-exploiting methods for (1) signal-selective high-resolution direction finding using sensor arrays, (2) selectively locating emitters by time difference and frequency difference measurement with one or more pairs of sensors, (3) identifying the kernels in the Volterra series representation of nonlinear time-invariant and multiply-periodic systems.

APPROXIMATE ANALYSIS ON STRAIN RATE EFFECTS AND BEHAVIOR OF STRESS AND STRAIN FIELDS AT THE CRACK TIP IN MODE 2 IN METALLIC MATERIALS, APPENDIX NO. 1
I. V. Varfolomeyev and J. R. Klepaczko Oct. 1992 97 p
(Contract DAJA45-90-C-0052)
(AD-A260836) Avail: CASI HC A05/MF A02

Analysis of conditions for crack initiation and fracture toughness in the case of metallic materials under various loading rates are problems of great interest in fracture mechanics. Several investigations have been carried out to reveal the loading rate effect on fracture toughness. At the same time, systematic analyses have been performed for a majority of structural materials to study strain rate effect on the yield stress, ultimate stress, material strain hardening, etc. Some correlations between fracture toughness and parameters of stress-strain diagram at different strain rates have been derived. The theoretical background of such correlations consists of solutions for elastic and elastic-plastic stress-strain fields near a crack tip. Analyses of stress distribution at the tip of a stationary crack under dynamic loading have been performed by Freund (1990) and Lee and Freund (1990). Another important application of fracture mechanics arises from a relationship between loading rate and specimen thickness for fracture toughness measurements.

A THREE-DIMENSIONAL MODEL FOR THE RESIDUAL STRESSES IN A UNIDIRECTIONAL COMPOSITE PLATE Ph.D. Thesis
Jianhui Liu 1992 132 p
Avail: Univ. Microfilms Order No. DA9236254

A three-dimensional (3-D) micromechanical model has been developed to represent a unidirectional composite plate that is subjected to a residual stress induced by temperature mismatch. The model assumes the fibers to be cylindrical inclusions that are periodically embedded into an epoxy matrix. At the interface of fiber and matrix, perfect bonding conditions are assumed to prevail. The method used in the thesis is based on a 3-D analytic investigation. The analytical solution shows the maximum stresses are located at theta = 0 for the graphite/epoxy composite plate. The location of the maximum stresses, however, may change for other material systems, particularly, for small shear moduli ratios mu(2)/mu(1). The solution also shows that the shear moduli ratio mu(2)/mu(1) (fiber to matrix), the geometric ratios a/h (fiber radius to thickness of the plate) and a/b (fiber radius to separation distance between adjacent fibers) have a great effect on the displacement and stress distributions. On the other hand, the ratio of thermal expansion coefficients alpha(2)/alpha(1) (fiber to matrix) presents a linear action to the displacement and stress fields. The stress profiles along a fiber length are shown to be constant except in neighborhood of the fiber edge where a boundary layer is shown to prevail. In the region, a stress singularity is confirmed that is a departure from the results given by macromechanical theories. In the limit, as a/b approaches 0, the result of one fiber model is recovered; as a/h approaches infinity the plane stress solution is recovered. Similarly, as mu(2)/mu(1) approaches 0 the result of a plate with a periodic array of holes is recovered.

DYNAMICS OF DEFORMABLE MULTIBODY SYSTEMS USING RECURSIVE PROJECTION METHODS Final Report, 30 Nov. 1989 - 29 Nov. 1992
A. A. Shabana Dec. 1992 13 p
(Contract DAAL03-90-G-0007)
(AD-A260698; ARO-26934.8-EG) Avail: CASI HC A03/MF A01

In this investigation, generalized Newton-Euler equations are developed for deformable bodies that undergo large translational and rotational displacements. The configuration of the deformable body is identified using coupled sets of reference and elastic variables. The nonlinear generalized Newton-Euler equations are formulated in terms of a set of time invariant scalars and matrices that depend on the spatial coordinates as well as the assumed displacement field. These time-invariant quantities appear in the nonlinear terms that represent the dynamic coupling between the rigid body modes and the elastic deformation. A set of recursive kinematic

equations, in which the absolute accelerations are expressed in terms of the joint and elastic accelerations are developed for several joint types. The recursive kinematic equations and the joint reaction relationships are combined with the generalized Newton-Euler equations in order to obtain a system of loosely coupled equations which have sparse matrix structure. Using matrix partitioning and recursive projection techniques based on optimal block factorization an order n solution for the system equations is obtained. DTIC

DESIGN OF FLEXIBLE RODS WITH EMBEDDED SMA ACTUATORS
H. J. Pfaeffle, Dimitris C. Lagoudas, Iradj Tadjbakhsh, and Kevin C. Craig 18 Jan. 1993 13 p
(Contract DAAL03-92-G-0123)
(AD-A260742; ARO-30378.5-EG-URI) Avail: CASI HC A03/MF A01

The shape change of a stress free cylindrical flexible rod with embedded SMA actuators is modeled in this paper for rods with single or multiple SMA actuators placed parallel to the long axis of the rod for the first heating the SMA actuators. The distributed axial compressive force, transverse normal force, and bending moments that act on the rod due to the shape recovery of the SMA actuators have been given by Lagoudas and Tadjbakhsh. The deformed shape of the rod is found by solving the nonlinear equations of equilibrium of the rod. For multiple actuators the resultant forces and moments are considered. A design analysis is performed for the active rod with a single SMA actuator. Key design variables are Erod, the thermal bond strength of the rod to the SMA actuator, and the rod dimensions. Key design parameters are: maximum rod/actuator interfacial shear stress, rod strain, rod slenderness ratio, and rod deflection. An analysis is then performed which investigates the influence of the design variables on each of the design parameters. DTIC

MICROMECHANICS OF FATIGUE Final Report, 15 Mar. 1989 - 14 Mar. 1992
Jean Lemaitre and Rene Billardon Jun. 1992 81 p
(Grant AF-AFOSR-0329-89)
(AD-A260577; Rept-134; AFOSR-93-0016TR) Avail: CASI HC A05/MF A01

In this final report, the results given in the first two annual reports are recalled. Application of the derived tools to Alpha-Two-Titanium Aluminide Alloy is made with a first series of strain controlled fatigue tests. The locally coupled model is first identified and then checked on a second series of stress controlled fatigue tests. The good agreement allows us to use this locally coupled method to predict fatigue crack initiation on brittle or quasibrittle materials. DTIC

OPTIMIZATION TECHNIQUES FOR CONTACT STRESS ANALYSIS M.S. Thesis
Eric S. McDonald Dec. 1992 90 p
(AD-A260846) Avail: CASI HC A05/MF A01

The analysis of stresses induced by contact between two bodies is inherently difficult because the size of the contact zone is unknown and constantly changing throughout loading. To overcome these difficulties, two approximation methods have been developed to determine the magnitude of contact stresses using the Rayleigh-Ritz method and the finite element method. Numerical optimization methods are employed to solve the contact problem. The solution techniques are compared to known analytical solutions and shown to yield accurate results. An application of this approach to solving the contact problem is illustrated by examining the response of a clamped sandwich composite beam to low velocity impact. It was found that the maximum shear stress is insensitive to lamina thickness, however an increase in the contact layer thickness resulted in a reduction in interfacial shear stress. In addition, it was noted that a nonlinear bending stress distribution in the contact layer intensified as the thickness of this layer increased. This phenomenon was found to be localized to the region of contact. Finally, it was found that the compressive transverse normal stresses increased as the thickness of the contact lamina increased. JOINT FLEXIBILITY EFFECTS ON THE DYNAMIC RESPONSE OF STRUCTURES. PART 2: STOCHASTIC ANALYSIS Final Report
Luis E. Suarez and Enrique E. Matheu Dec. 1992 66 p
(Contract DAAL03-90-G-0214)
(AD-A261003; ARO-28374.6-EG-H-Pt-2) Avail: CASI HC A04/MF A01

The objective of this study is to quantify the effect of flexible connections with random stiffness on the modal properties and dynamic response of structures. Since the mass and stiffness matrices contain random parameters, the modal decomposition solution of the equations of motion lead to a random eigenvalue problem. A second order perturbation technique is used for the solution of the random eigenproblem. Closed form expressions for the mean and variance of the natural frequencies and vibration modes are provided. The response of systems with random parameters subjected to deterministic loads is examined next beginning with single degree of freedom systems. When standard perturbation methods are applied to calculate the statistics of the response, the expressions obtained become nonuniform as time grows. A detailed discussion about the cause of the problem is presented. A new formulation based on the method of multiple scales used for nonlinear systems is proposed to overcome the problem. The response analysis is extended to multi-degree-of-freedom systems. Conclusions and recommendations for further research are presented. DTIC

VARIATIONAL THEORY OF MOTION OF CURVED, TWISTED AND EXTENSIBLE ELASTIC RODS Technical Report
Iradj Tadjbakhsh and Dimitris C. Lagoudas 18 Jan. 1993 15 p
(Contract DAAL03-92-G-0123)
(AD-A261028; ARO-30378.6-EG-URI) Avail: CASI HC A03/MF A01

The variational theory of three dimensional motion of curved twisted and extensible elastic rods is obtained based entirely on the kinematical variables of position and rotations. The constitutive relations that define the resistive couples and the axial force as gradients of the strain energy function are established. A candidate for the strain energy function, derived on the basis of classical assumptions, is presented. DTIC

DEFORMATIONS OF ACTIVE FLEXIBLE RODS WITH EMBEDDED LINE ACTUATORS
D. C. Lagoudas and I. G. Tadjbakhsh 18 Jan. 1993 30 p
(Contract DAAL03-92-G-0123)
(AD-A261207; ARO-30378.8-EG-URI) Avail: CASI HC A03/MF A01

The 3-D formulation of flexible rods with embedded line actuators is presented in this paper. Both the rods and the line actuator are assumed to be initially curved and relatively positioned in an arbitrary way. The deformed configurations of the rod and actuator are connected by assuming that the principal planes of the rod remain in plane and inextensible in the deformed configuration. The resultant forces and moments in the rod and actuator are found by solving the equilibrium equations for both the rod and actuator and applying continuity of tractions on the rod-actuator interface. The formulation is reduced to 2-D and applied to the case of a Shape Memory Alloy (SMA) fiber embedded in a cylindrical rod. The deformed shapes of the rod under repeated thermal actuation and the resulting shape memory loss due to the development of residual stresses are evaluated. Finally, the inverse problem of finding the required actuation force and initial curvature, to acquire a predetermined deformed shape, is solved in closed form for the 2-D cases. DTIC

US-Patent-Appl-SN-797507; US-Patent-Class-73-788;
US-Patent-Class-73-641; Int-Patent-Class-G01N-3/00) Avail: US Patent and Trademark Office

An ultrasonic wave is applied to an anisotropic sample material in an initial direction and an angle of flux deviation of the ultrasonic wave front is measured from this initial direction. This flux deviation angle is induced by the unknown applied load. The flux shift is determined between this flux deviation angle and a previously determined angle of flux deviation of an ultrasonic wave applied to a similar anisotropic reference material under an initial known load condition. This determined flux shift is then compared to a plurality of flux shifts of a similarly tested, similar anisotropic reference material under a plurality of respective, known load conditions, whereby the load applied to the particular anisotropic sample material is determined. A related method is disclosed for determining the fiber orientation from known loads and a determined flux shift.

ANALYSIS OF SHAPED CHARGE JET PENETRATION EXPERIMENTS WITH PEN

S. Christian Simonson, III May 1992 33 p

(Contract W-7405-eng-48)

(UCRL-LR-110773) Avail: CASI HC A03/MF A01

The 'Pen' computer program has been applied to the analysis of two shaped charge jet penetration experiments. This analysis has served as a test of the Pen algorithms and as an illustration of the methods of applying the code. As part of the analysis, an experimental value of 14.4 +/- 1.9 kbar has been obtained for the effective strength of hardened A4340 steel under jet impact. From radiographs and hydrocode calculations, the critical radius at breakup of the copper jets in these experiments was found to follow a linear relationship, r(sub cr) = 3.5 x 10(exp -4) 1.9 x 10(exp -6) (t - t(sub 0)), where r(sub cr) is expressed in charge diameters and (t - t(sub 0)) is the time in microsec referred to the virtual origin of the jet. (These coefficients may vary by a factor of 2 depending on design and manufacture.) Timing data from embedded foil switches yielded a set of penetration efficiency factors, which varied between 1.34 near the tip to 0.78 near the tail. Interference was found to set in at a constriction point a few centimeters inside the target entrance. By matching the jet arrival times and the hole profiles for the primary penetration, the effective strength of the steel was obtained. The increase of about 25 percent above the nominal yield strength of 11.5 kbar is attributed to work hardening and pressure effects. Author

ALGORITHMS FOR THE ANALYSIS OF PENETRATION BY SHAPED CHARGE JETS

S. Christian Simonson, III Apr. 1992 35 p

(Contract W-7405-eng-48)

(UCRL-LR-109887) Avail: CASI HC A03/MF A01

A set of algorithms has been developed for the analysis of penetration by shaped charge jets into homogeneous armor targets. Standard expressions are included for calculating the depth of penetration by a stretching jet (Bernoulli's equation) and for calculating the radius of the hole (by means of an energy balance). Special methods are developed for calculating the onset of particulation and for calculating the depth of penetration by the particulated portion of a jet. These methods are provided in order to evaluate the performance of new types of jets, some of which have unconventional mass and velocity distributions that are unsuited to analysis by previous methods. In particular, the onset of breakup for each portion of the jet is calculated by treating the critical radius as a linear function of the inverse local stretching rate. A method for calculating interference with the hole is included, and the jet profile for maximum penetration is derived. Author

FABRICATION OF COMPOSITE PROPFAN BLADES FOR A CRUISE MISSILE WIND TUNNEL MODEL

E. Brian Fite Apr. 1993 30 p

(RTOP 535-03-10)

(NASA-TM-105270; E-7327; NAS 1.15:105270) Avail: CASI HC A03/MF A01

This report outlines the procedures that were employed in fabricating prototype graphite-epoxy composite prop fan blades. These blades were used in wind tunnel tests that investigated prop fan propulsion system interactions with a missile airframe in order to study the feasibility of an advanced-technology-propfan-propelled missile. Major phases of the blade fabrication presented include machining of the master blade, mold fabrication, ply cutting and assembly, blade curing, and quality assurance. Specifically, four separate designs were fabricated, 18 blades of each geometry, using the same fabrication technique for each design. Author

IMPROVED FATIGUE LIFE FOR MOORINGS

R. J. Seymour and S. A. Massey Dec. 1992 25 p

(Grant NA89AA-D-SG138; Proj. NOAA-R/OE-14)

(PB93-161198; SIO-REF-92-33) Avail: CASI HC A03/MF A01

Moorings are ubiquitous in man's useful occupation of the ocean. They are used to secure instruments and other unattended apparatus for scientific, civil and military uses and to fix the location for various lengths of time of manned platforms for mineral and hydrocarbon extraction and for marine transportation and ocean construction applications. Subject to wave and current loads, vibration from eddy shedding, and a hostile chemical environment, moorings fatigue and eventually fail if not replaced in time. The research is directed toward significantly improving the reliability and the service life of ocean mooring systems by developing the use of nonconventional materials (particularly advanced composites) and constructions. The work will extend previous and present research by the investigators in highly related areas. Subscale mooring elements (lines, terminations, and flexures) will be tested for fatigue resistance in a seawater environment in the laboratory. The overall project objective is to make substantial improvements in the service life and reliability of ocean moorings by using materials and constructions that are significantly less sensitive to fatigue and stress corrosion than conventional components. EXPERIMENTAL STUDIES OF STRESS MANAGEMENT BY OPTICAL FLUORESCENCE Annual Report

David R. Clarke Dec. 1992 90 p

(Contract N00014-91-J-1875)

(AD-A261539) Avail: CASI HC A05/MF A01

In this program the measurement of stresses in ceramics using their optical fluorescence is being developed. The technique is based on the phenomena of piezospectroscopy, namely the shift in optical fluorescence of a material produced by a stress. In the course of the program to data we have derived for the first time a general relationship between an observed shift in fluorescence frequency and the state of stress, applied it to the

determination of both applied and residual stresses in single crystal and polycrystalline materials, and begun to exploit the technique to the measurement of stresses in a variety of composite materials. These are described in detail in the accompanying technical reports appended here. As part of this investigation we have also found that in ruby (Chromium(3+) doped sapphire) the observed optical fluorescence shift as a function of chromium concentration is a direct measure of the 'image stress'.

J AND CTOD ESTIMATION EQUATIONS FOR SHALLOW CRACKS IN SINGLE EDGE NOTCH BEND SPECIMENS
Mark T. Kirk and Robert H. Dodds, Jr. Jan. 1993 28 p
(Contract N61533-92-R-0030)
(AD-A261679; UILU-ENG-91-2013; CDNSWC/SME-CR-17-92; NUREG-CR-5669) Avail: CASI HC A03/MF A01

Results from two dimensional plane strain finite-element analyses are used to develop J and CTOD estimation strategies appropriate for application to both shallow and deep crack SE(B) specimens. Crack depth to specimen width (a/W) ratios between 0.05 and 0.70 are modelled using Ramberg-Osgood strain hardening exponents (n) between 4 and 50. The estimation formulas divide J and CTOD into small scale yielding (SSY) and large scale yielding (LSY) components. For each case, the SSY components is determined by the linear elastic stress intensity factor, K(sub I). The formulas differ in evaluation of the LSY component. The techniques considered include: estimating J or CTOD from plastic work based on load line displacement (A(sub pl)/ILLD), from plastic work based on crack mouth opening displacement (A(sub pl)/CMOD(sub pl)), and from the plastic component of crack mouth opening displacement (CMOD(sub pl)). A(sub pl)CMOD provides the most accurate J estimation possible. CTOD estimates based on scalar proportionality of CTOD(sub Isy) and CMOD(sub pl) are highly inaccurate, especially for materials with considerable strain hardening, where errors up to 38% occur. BEHAVIOR OF A STEEL-LINER-AND-BOLTS SYSTEM UNDER VERY HIGH THERMAL AND MECHANICAL LOADING: THE CONVEX LINER ADD-ON TO DIAMOND FORTUNE
F. E. Heuze, R. P. Swift, L. R. Hill (Sandia National Labs., Albuquerque, NM.), and W. H. Barrett (Sandia National Labs., Albuquerque, NM.) Jan. 1993 13 p Presented at the Symposium on Numerical Modeling Applications in Mining and Geomechanics, Montreal, Quebec, 27-30 Mar. 1993
(Contracts W-7405-eng-48; DE-AC04-76DP-00789)
(DE93-007512; UCRL-JC-112455; CONF-9303102-1) Avail: CASI HC A03/MF A01

This work involved the response of a liner-bolt system installed on the wall of the DIAMOND FORTUNE cavity, a 22-m diameter nearly semi-spherical chamber in tuff, at the Nevada Test Site. DIAMOND FORTUNE is a low-yield nuclear test of the Defense Nuclear Agency which was performed in April, 1992. A 1.4-m square, 2.5-cm thick steel plate was anchored by 9-m long bolts: four 2.5-cm diameter bolts at the corners and a 5-cm diameter bolt at the center. The bolt ends daylighted in a tunnel surrounding the cavity, and were tensioned from there. The system was aped with 20 data channels for strain, acceleration, contact pressure, and temperature. We relate the thermal analyses and the 3-dimensional dynamic analyses performed for this project, and we present the test results which indicated the excellent response of this system to the high dynamic loads and temperatures. APPROXIMATE TECHNIQUES FOR PREDICTING SIZE EFFECTS ON CLEAVAGE FRACTURE TOUGHNESS (J(SUB c)) Final Report
Mark T. Kirk and Robert H. Dodds, Jr. Jan. 1993 40 p
(Contract N61533-92-R-0030)
(AD-A261591; UILU-ENG-92-2016; CDNSWC/SME-CR-18-92; NUREG/CR-5970) Avail: CASI HC A03/MF A01

This investigation examines the ability of an elastic T-stress coupled with a modified boundary layer (MBL) solution to predict stresses ahead of a crack tip in a variety of planar geometries. The approximate stresses are used as input to estimate the effective driving force for cleavage fracture (J(sub o)) using the micromechanically based approach. Finite element analyses for a wide variety of planar cracked geometries are conducted which have elastic biaxiality parameters (beta) ranging from -0.99 (very low constraint) to +2.96 (very high constraint). The magnitude and sign of beta indicate the rate at which crack-tip constraint changes with increasing applied load. All results pertain to a moderately strain hardening material (strain hardening exponent (n) of 10). These analyses suggest that beta is an effective indicator of both the accuracy of T-MBL estimates of J(sub o) and of applicability limits on evolving fracture analysis methodologies (i.e. T-MBL, J-Q, and J/J(sub o)). USE AND ANALYSIS OF FINITE ELEMENT METHODS FOR PROBLEMS OF SOLID MECHANICS AND FRACTURE Final Report, Sep. 1989 - Nov. 1992
J. R. Whiteman 19 Jan. 1993 8 p LIMITED REPRODUCIBILITY: More than 20% of this document may be affected by microfiche quality
(Contract DAJA45-89-C-0023)
(AD-A261574; Rept-6078-MA-01) Avail: CASI HC A02

In this project, the principal investigator and his co-workers wish to exploit their expertise in the theoretical analysis, particularly regarding superconvergence, and practical application of finite element methods to produce and analyze new finite element schemes for treating difficult linear and nonlinear problems of solid mechanics and fracture mechanics. The difficulties arise from the presence of effects such as material nonlinearities, nonhomogeneity, time dependence, and stationary and moving cracks. In particular, they wish to apply new retrieval techniques of finite elements to define new adaptive procedures for producing numerical solutions with enhanced properties for some problems of linear elasticity and linear elastic fracture, elasto-plasticity and nonlinear fracture, viscoelasticity, and viscoelastic fracture. Contexts in which these new techniques will be applied include the deformation and fracture of timbers, and elasto-plastic deformation and fracture of metals with work hardening and the viscoelastic deformation and fracture of various polymers. Attention will also be given to some composite structures in these contexts. Whenever possible the numerical results will be compared with experimental results. DTIC

The influence of primary orientation on the elastic response of a (001)-oriented nickel-base single-crystal superalloy, PWA 1480, was investigated under mechanical, thermal, and combined thermal and mechanical loading conditions using finite element techniques. Elastic stress analyses were performed using the MARC finite element code on a square plate of PWA 1480 material. Primary orientation of the single crystal

superalloy was varied in increments of 2 deg, from 0 to 10 deg, from the (001) direction. Two secondary orientations (0 and 45 deg) were considered, with respect to the global coordinate system, as the primary orientation angle was varied. The stresses developed within the single crystal plate were determined for each loading condition. In this paper, the influence of the angular offset between the primary crystal orientation and the loading direction on the elastic stress response of the PWA 1480 plate is presented for different loading conditions. The influence of primary orientation angle, when constrained between the bounds considered, was not found to be as significant as the influence of the secondary orientation angle, which is not typically controlled. The First Consultative Meeting on Responsible National Oceanographic Data Centres (RNODC's) and Climate DataServices met in February 1988 and made a number of recommendations related to improving services to meet the needs of climate programmes. Included in these discussions was a recommendation for a Workshop on Ocean Climate Data Management. This workshop will be talking about ways to establish a Global Ocean Observing System (GOOS). For individual titles, see N93-24916 through N93-24942.

Avail: CASI HC A03/MF A03

Local application of global-scale models describes the U.S. Navy's basic philosophy for operational oceanography in support of fleet operations. Real-time data, climatologies, coupled air/ocean models, and large scale computers are the essential components of the Navy's system for providing the war fighters with the performance predictions and tactical decision aids they need to operate safely and efficiently. In peacetime, these oceanographic predictions are important for safety of navigation and flight. The paucity and uneven distribution of real-time data mean we have to fall back on climatology to provide the basic data to operate our models. The Navy is both a producer and user of climatologies; it provides observations to the national archives and in turn employs data from these archives to establish data bases. Suggestions for future improvements to ocean climate data are offered. Author

INTERNATIONAL ORGANISATION OF OCEAN PROGRAMS: MAKING A VIRTUE OF NECESSITY **c48**

Angus McEwan *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 45-49 (For primary document see N93-24915 09-42)

Avail: CASI HC A01/MF A03

When faced with the needs of climate prediction, a sharp contrast is revealed between existing networks for the observation of the atmosphere and for the ocean. Even the largest and longest-serving ocean data networks were created for their value to a specific user (usually with a defence, fishing or other maritime purpose) and the major compilations of historical data have needed extensive scientific input to reconcile the differences and deficiencies of the various sources. Vast amounts of such data remain inaccessible or unusable. Observations for research purposes have been generally short lived and funded on the basis of single initiatives. Even major programs such as FGGE, TOGA and WOCE have been driven by the dedicated interest of a surprisingly small number of individuals, and have been funded from a wide variety of temporary allocations. Recognising the global scale of ocean observations needed for climate research, international cooperation and coordination is an unavoidable necessity, resulting in the creation of such bodies as the Committee for Climatic Changes and the Ocean (CCCO), with the tasks of: (1) defining the scientific elements of research and ocean observation which meet the needs of climate prediction and amelioration; (2) translating these elements into terms of programs, projects or requirements that can be understood and participated in by individual nations and marine agencies; and (3) the sponsorship of specialist groups to facilitate the definition of research programs, the implementation of cooperative international activity and the dissemination of results. ROLE OF THE OCEAN IN CLIMATE CHANGES **c48**

Sergey K. Gulev *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 51-64 (For primary document see N93-24915 09-42)

Avail: CASI HC A03/MF A03

The present program aimed at the study of ocean climate change is prepared by a group of scientists from State Oceanographic Institute, Academy of Science of Russia, Academy of Science of Ukraine and Moscow State University. It appears to be a natural evolution of ideas and achievements that have been developed under national and international ocean research projects such as SECTIONS, WOCE, TOGA, JGOFS and others. The two primary goals are set in the program ROCC. (1) Quantitative description of the global interoceanic 'conveyor' and it's role in formation of the large scale anomalies in the North Atlantic. The objectives on the way to this goal are: to get the reliable estimates of year-to-year variations of heat and water exchange between the Atlantic Ocean and the atmosphere; to establish and understand the physics of long period variations in meridianal heat and fresh water transport (MHT and MFWT) in the Atlantic Ocean; to analyze the general mechanisms, that form the MHT and MFWT in low latitudes (Ekman flux), middle latitudes (western boundary currents) and high latitudes (deep convection) of the North Atlantic; to establish and to give quantitative description of the realization of global changes in SST, surface salinity, sea level and sea ice data. (2) Development of the observational system pointed at tracing the climate changes in the North Atlantic. This goal merges the following objectives: to find the proper sites that form the inter annual variations of MHT; to study the deep circulation in the 'key' points; to develop the circulation models reflecting the principle features of interoceanic circulation; and to define global and local response of the atmosphere circulation to large scale processes in the Atlantic Ocean. THE ROLE OF THE WORLD DATA CENTERS IN HANDLING OCEAN CLIMATE DATA **c48**

Ferris Webster *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 65-73 (For primary document see N93-24915 09-42)

Avail: CASI HC A02/MF A03

The World Data Center System, set up for the International Geophysical Year in 1957, is an international network of data centers that links data contributors to data users in the geosciences. It includes means for the synthesis, analysis, and preparation of data products. It was set up in response to the needs of the international scientific community, and is still

overseen by non-governmental scientific organizations. Because it is freely available to researchers in all countries, the World Data Center System has a special role to play in support of ocean climate research and monitoring programs. The World Data Centers face a number of challenges today. Apathy is probably the greatest, since many scientists take the system for granted. There is need to improve access and exploit new technology. The system must establish new links to assure continuity in a world with political changes. The multidisciplinary needs of global change research will demand capabilities for data and information management that go beyond the traditional emphasis on geophysics. Author

THE GLOBAL OCEAN OBSERVING SYSTEM: ONE PERSPECTIVE c48

J. Ron Wilson *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 79-84 (For primary document see N93-24915 09-42)

Avail: CASI HC A02/MF A03

This document presents a possible organization for a Global Ocean Observing System (GOOS) within the Intergovernmental Oceanographic Commission and the joint ocean programs with the World Meteorological Organization. The document and the organization presented here is not intended to be definitive, complete or the best possible organization for such an observation program. It is presented at this time to demonstrate three points. The first point to be made is that an international program office for GOOS along the lines of the WOCE and TOGA IPOs is essential. The second point is that national programs will have to continue to collect data at the scale of WOCE plus TOGA and more. The third point is that there are many existing groups and committees within the IOC and joint IOC/WMO ocean programs that can contribute essential experience to and form part of the basis of a Global Ocean Observing System. It is particularly important to learn from what has worked and what has not worked in the past if a successful ocean observing system is to result. Author (revised)

OPERATIONAL SEASONAL AND INTERANNUAL PREDICTIONS OF OCEAN CONDITIONS c48

Ants Leetmaa *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 85-86 (For primary document see N93-24915 09-42)

Avail: CASI HC A01/MF A03

Dr. Leetmaa described current work at the U.S. National Meteorological Center (NMC) on coupled systems leading to a seasonal prediction system. He described the way in which ocean thermal data is quality controlled and used in a four dimensional data assimilation system. This consists of a statistical interpolation scheme, a primitive equation ocean general circulation model, and the atmospheric fluxes that are required to force this. This whole process generated dynamically consist thermohaline and velocity fields for the ocean. Currently routine weekly analyses are performed for the Atlantic and Pacific oceans. These analyses are used for ocean climate diagnostics and as initial conditions for coupled forecast models. Specific examples of output products were shown both in the Pacific and the Atlantic Ocean. Derived from text

WORLD OCEAN CIRCULATION EXPERIMENT c48

R. Allyn Clarke *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 87-94 (For primary document see N93-24915 09-42)

Avail: CASI HC A02/MF A03

The oceans are an equal partner with the atmosphere in the global climate system. The World Ocean Circulation Experiment is presently being implemented to improve ocean models that are useful for climate prediction both by encouraging more model development but more importantly by providing quality data sets that can be used to force or to validate such models. WOCE is the first oceanographic experiment that plans to generate and to use multiparameter global ocean data sets. In order for WOCE to succeed, oceanographers must establish and learn to use more effective methods of assembling, quality controlling, manipulating and distributing oceanographic data. Author

THE GLOBAL OCEAN OBSERVING SYSTEM Abstract Only c48

Dana Kester *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 95 (For primary document see N93-24915 09-42)

Avail: CASI HC A01/MF A03

A Global Ocean Observing System (GOOS) should be established now with international coordination (1) to address issues of global change, (2) to implement operational ENSO forecasts, (3) to provide the data required to apply global ocean circulation models, and (4) to extract the greatest value from the one billion dollar investment over the next ten years in ocean remote sensing by the world's space agencies. The objectives of GOOS will focus on climatic and oceanic predictions, on assessing coastal pollution, and in determining the sustainability of living marine resources and ecosystems. GOOS will be a complete system including satellite observations, in situ observations, numerical modeling of ocean processes, and data exchange and management. A series of practical and economic benefits will be derived from the information generated by GOOS. In addition to the marine science community, these benefits will be realized by the energy industries of the world, and by the world's fisheries. The basic oceanic variables that are required to meet the oceanic and predictability objectives of GOOS include wind velocity over the ocean, sea surface temperature and salinity, oceanic profiles of temperature and salinity, surface current, sea level, the extent and thickness of sea ice, the partial pressure of CO2 in surface waters, and the chlorophyll concentration of surface waters. Ocean circulation models and coupled ocean-atmosphere models can be used to evaluate observing system design, to assimilate diverse data sets from in situ and remotely sensed observations, and ultimately to predict future states of the system. The volume of ocean data will increase enormously over the next decade as new satellite systems are launched and as complementary in situ measuring systems are deployed. These data must be transmitted, quality controlled, exchanged, analyzed, and archived with the best state-of-the-art computational methods. Author

GLOBAL TEMPERATURE AND SALINITY PILOT PROJECT c48

Ben Searle *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 97-108 (For primary document see N93-24915 09-42)

Avail: CASI HC A03/MF A03

Data exchange and data management programs have been evolving over many years. Within the international community there are two main programs to support the exchange, management and processing of real time and delayed mode data. The Intergovernmental Oceanographic Commission (IOC) operate the International Oceanographic Data and Information Exchange (IODE) program which coordinates the exchange of delayed mode data between national oceanographic data centers, World Data Centers and the user community. The Integrated Global Ocean Services System is a joint IOC/World Meteorological Organization (WMO) program for the exchange and management of real-time data. These two programs are complemented by mechanisms that have been established within scientific programs to exchange and manage project data sets. In particular TOGA and WOCE have identified a data management requirement and established the appropriate infrastructure to achieve this. Where GTSPP fits into this existing framework is discussed. INDIAN OCEAN ANALYSES c48

Gary Meyers *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 109-129 (For primary document see N93-24915 09-42)

Avail: CASI HC A03/MF A03

The background and goals of Indian Ocean thermal sampling are discussed from the perspective of a national project which has research goals relevant to variation of climate in Australia. The critical areas of SST variation are identified. The first goal of thermal sampling at this stage is to develop a climatology of thermal structure in the areas and a description of the annual variation of major currents. The sampling strategy is reviewed. Dense XBT sampling is required to achieve accurate, monthly maps of isotherm-depth because of the high level of noise in the measurements

caused by aliasing of small scale variation. In the Indian Ocean ship routes dictate where adequate sampling can be achieved. An efficient sampling rate on available routes is determined based on objective analysis. The statistical structure required for objective analysis is described and compared at 95 locations in the tropical Pacific and 107 in the tropical Indian Oceans. XBT data management and quality control methods at CSIRO are reviewed. Results on the mean and annual variation of temperature and baroclinic structure in the South Equatorial Current and Pacific/Indian Ocean Throughflow are presented for the region between northwest Australia and Java-Timor. The mean relative geostrophic transport (0/400 db) of Throughflow is approximately 5 x 106 m3/sec. A nearly equal volume transport is associated with the reference velocity at 400 db. The Throughflow feeds the South Equatorial Current, which has maximum westward flow in August/September, at the end of the southeasterly Monsoon season. A strong semiannual oscillation in the South Java Current is documented. The results are in good agreement with the Semtner and Chervin (1988) ocean general circulation model. The talk concludes with comments on data inadequacies (insufficient coverage, timeliness) particular to the Indian Ocean and suggestions on the future role that can be played by Data Centers, particularly with regard to quality control of data as research bodies are replaced by operational bodies in the Global Ocean Observing System. THE USE OF REMOTELY SENSED DATA FOR OPERATIONAL FISHERIES OCEANOGRAPHY **c48**
Armando F. G. Fiuza *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 145-152 Sponsored in part by Commission of the European Communities (For primary document see N93-24915 09-42)
Avail: CASI HC A02/MF A03

Satellite remote sensing data are used under two contexts in fisheries: as a tool for fisheries research and as a means to provide operational support to fishing activities. Fishing operations need synoptic data provided timely; fisheries research needs that type of data and, also, good short-term climatologies. A description is given of several experiences conducted around the world which have employed or are using satellite data for operational fisheries problems. An overview is included of the Portuguese program for fisheries support using remotely sensed data provided by satellites and in situ observations conducted by fishermen. Environmental products useful for fisheries necessarily combine satellite and in situ data. The role of fishermen as a source of good, near-real-time in situ environmental data is stressed; so far, this role seems to have been largely overlooked. Author

OCEAN-PC AND A DISTRIBUTED NETWORK FOR OCEAN DATA **c48**
Douglas R. McLain *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 153-160 (For primary document see N93-24915 09-42)
Avail: CASI HC A02/MF A03

The Intergovernmental Oceanographic Commission (IOC) wishes to develop an integrated software package for oceanographic data entry and access in developing countries. The software, called 'OCEAN-PC', would run on low cost PC microcomputers and would encourage and standardize: (1) entry of local ocean observations; (2) quality control of the local data; (3) merging local data with historical data; (4) improved display and analysis of the merged data; and (5) international data exchange. OCEAN-PC will link existing MS-DOS oceanographic programs and data sets with table-driven format conversions. Since many ocean data sets are now being distributed on optical discs (Compact Discs - Read Only Memory, CD-ROM, Mass et al. 1987), OCEAN-PC will emphasize access to CD-ROMs.

SEA LEVEL VARIATION Abstract Only **c48**
Bruce C. Douglas *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 161 (For primary document see N93-24915 09-42)
Avail: CASI HC A01/MF A03

Published values for the long-term, global mean sea level rise determined from tide gauge records range from about one to three mm per year. The scatter of the estimates appears to arise largely from the use of data from gauges located at convergent tectonic plate boundaries where changes of land elevation give fictitious sea level trends, and the effects of large interdecadal and longer sea level variations on short (less than 50+ years) or sappy records. In addition, virtually all gauges undergo subsidence or uplift due to isostatic rebound from the last deglaciation at a rate comparable to or greater than the secular rise of sea level. Modeling rebound by the ICE-3G model of Tushingham and Peltier (1990) and avoiding tide gauge records in areas of converging tectonic plates produces a highly consistent set of long sea level records. A global set of 21 such stations in nine oceanic regions with an average record length of 76 years during the period 1880-1980 yields the global sea level rise value 1.8 mm/year +/- 0.1. Greenhouse warming scenarios commonly forecast an additional acceleration of global sea level in the next 5 or 6+ decades in the range 0.1-0.2 mm/yr2. Because of the large power at low frequencies in the sea level spectrum, very long tide gauge records (75 years minimum) have been examined for past apparent sea level acceleration. For the 80-year period 1905-1985, 23 essentially complete tide gauge records in 10 geographic groups are available for analysis. These yielded the apparent global acceleration -0.011 (+/- 0.012) mm/yr2. A larger, less uniform set of 37 records in the same 10 groups with 92 years average length covering the 141 years from 1850-1991 gave 0.001 (+/- 0.008) mm/yr2. Thus there is no evidence for an apparent acceleration in the past 100+ years that is significant either statistically, or in comparison to values associated with global warming. Unfortunately, the large interdecadal fluctuations of sea level severely affect estimates of global sea level acceleration for time spans of less than about 50 years. This means that tide gauges alone cannot serve as a reliable leading indicator of climate change in less than many decades. This time required can be significantly reduced if the interdecadal fluctuations of sea level can be understood in terms of their forcing mechanisms, and then removed from the tide gauge records.

SATELLITE ALTIMETRY **c43**
Robert E. Cheney *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 169-170 (For primary document see N93-24915 09-42)
Avail: CASI HC A01/MF A03

Since altimetry data are not really old enough to use the term data archaeology, Mr. Cheney referred to the stewardship of these data. He noted that it is very important to document the basis for an altimetry data set as the algorithms and corrections used to arrive at the Geophysical Data Record (GDR) have been improving and are continuing to improve the precision of sea level data derived from altimetry. He noted that the GEOSAT Exact Repeat Mission (ERM) data set has recently been reprocessed by his organization in the National Ocean Service of NOAA and made available to the scientific community on CD/ROM disks by the National Oceanographic Data Center of the U.S. (NODC). The new data set contains a satellite orbit more precise by an order of magnitude together with an improved water vapor correction. A new, comprehensive GDR Handbook has also been prepared. DATA ARCHAEOLOGY AT ICES **c82**
Harry D. Dooley *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 173-185 (For primary document see N93-24915 09-42)
Avail: CASI HC A03/MF A03

This paper provides a brief overview of the function of the International Council for the Exploration of the Sea (ICES), both past and present, in particular in the context of its interest in compiling oceanographic data sets. Details are provided of the procedures it adopted to ensure adequate internationally collaborative marine investigations during the first part of the century, such as how it provided a forum for action by its member states, how it coordinated and published the results of scientific programs, and how it provided a foundation, through scientists employed in the ICES Office, for the establishment of the original oceanographic marine databases and associated products, and the scientific interpretation of the results. The growth and expansion of this area of ICES activity is then traced, taking into account the changing conditions for oceanographic data management resulting from the establishment of the National Data Centres, as well as the World Data Centres for Oceanography, which were created to meet the needs of the International Geophysical Year (IGY). Finally, there is a discussion of the way in which the very existence of ICES has proved to be a valuable source of old data, some of which have not yet been digitized, but which can be readily retrieved because they have been very carefully documented throughout the years. Lessons from this activity are noted, and suggestions are made on how the past experiences of ICES can be utilized to ensure the availability of marine data to present and future generations of scientists. Acquisition of data on the ocean is believed to start in 1872, when the Royal Navy ship 'Challenger' performed oceanographic stations in its round-world voyage (1872-1876). The first oceanographic studies of the World Ocean refer to the 80s second half of the 19th century. During its round-world expedition 'Vityaz' (1886-1889) headed by S.O. Markov, performed hydrological measurements in the Baltic Sea, Atlantic and Pacific Oceans. According to information available the regular expedition observations (prototype of future complex international program on the ocean research) started in the second half of 80s last century under the auspice of Kiev commission for exploration of German Seas. Systematic hydrological observations were organized by Hydrographic Department of Russia in 1876-1879 according to the program similar to the Kiev one and observations were regularly made by ships of custom service over the Russian area of the Baltic Sea. The increasing demands in oceanographic data contributed to considerable progress in exploration of the World Ocean during current century whole tendency to increase and become more significant has been observed for the last 30-40 years. Most probably various expeditions which were carried out during International Geophysical Year in different regions of the World Ocean are to be reference point in performing intensive oceanographic observations of Marine environment. In the former USSR oceanographic observations are made by research and hydrographic vessels, commercial and fishery ships as well as oil production platforms, coastal hydrometeorological station and other observing platforms. Oceanographic observations data, available from main sources of information on the ocean-research vessels, are also considered in the report.

OCEAN CLIMATE DATA FOR USER COMMUNITY IN WEST AND CENTRAL AFRICA: NEEDS, OPPORTUNITIES, AND CHALLENGES **c82**

S. O. Ojo *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 193-199 (For primary document see N93-24915 09-42)

Avail: CASI HC A02/MF A03

The urgent need to improve data delivery systems needed by scientists studying ocean role in climate and climate characteristics has been manifested in recent years because of the unprecedented climatic events experienced in many parts of the world. Indeed, there has been a striking and growing realization by governments and the general public indicating that national economies and human welfare depend on climate and its variability. In West and Central Africa, for instance climatic events, which have resulted in floods and droughts, have caused a lot of concern to both governments and people of the region. In particular, the droughts have been so widespread that greater awareness and concern have become generated for the need to find solutions to the problems created by the consequences of the climatic events. Particularly in the southern border regions of the Sahara Desert as well as in the Sahel region, the drought episodes considerably reduced food production and led to series of socioeconomic problems, not only in the areas affected by the droughts, but also in the other parts of West Africa. The various climatic variabilities which have caused the climatic events are no doubt related to the ocean-atmosphere interactions. Unfortunately, not much has been done on the understanding of these interactions, particularly as they affect developing countries. Indeed, not much has been done to develop programs which will reflect the general concerns and needs for researching into the ocean-atmosphere systems and their implications on man-environmental systems in many developing countries. This is for example, true of West and Central Africa, where compared with the middle latitude countries, much less is known about the characteristics of the ocean-atmosphere systems and their significance on man-environmental systems of the area.

THE JGOFS NORTH ATLANTIC BLOOM EXPERIMENT: AN OVERVIEW **c48**

Hugh W. Ducklow *In* NASA. Goddard Space Flight Center, Proceedings of the Ocean Climate Data Workshop 1992 p 205-227 (For primary document see N93-24915 09-42)

Avail: CASI HC A03/MF A03

The North Atlantic Bloom Experiment (NABE) of JGOFS presents a unique opportunity and challenge to the data management community because of the diversity and large size of biogeochemical data sets collected. NABE was a pilot study for JGOFS and has also served as a pilot study within the U.S. NODC for management and archiving of the data sets. Here I present an overview to some of the scientific results of NABE, which will be published as an Introduction to a special volume of NABE results in Deep-Sea Research later this year. An overview of NABE data management is given elsewhere in the present report. This is the first collection of papers from the Joint Global Ocean Flux Study (JGOFS). Formed as an international program in 1987, JGOFS has four principal elements: modelling and data management, multidisciplinary regional process studies, a global survey of biogeochemical properties and long-term time series observatories. In 1989-1990 JGOFS conducted a pilot process study of the spring phytoplankton bloom, the North Atlantic Bloom Experiment (NABE). JGOFS decided to conduct a large scale, internationally-coordinated pilot study in the North Atlantic because of its proximity to the founding nations of the project, the size and predictability of the bloom and its fundamental impact on ocean bio-geochemistry (Billett et al., 1983; Watson and Whitfield, 1985; Pfannkuche, 1992). In 1989, six research vessels from Canada, Germany, The Netherlands, the United Kingdom and the USA and over 200 scientists and students from more than a dozen nations participated in NABE. Some of their initial results are reported in this volume.

The Joint Global Ocean Flux Study (JGOFS), currently being organized under the auspices of the Scientific Committee for Ocean Research (SCOR), is intended to be a decade long internationally coordinated program. The main goal of JGOFS is to determine and understand on a global scale the processes controlling the time-varying fluxes of carbon and associated biogenic elements in the ocean and to evaluate the related exchanges with the atmosphere, sea floor and continental boundaries. 'A long-term goal of JGOFS will be to establish strategies for observing, on long time scales, changes in ocean biogeochemical cycles in relation to climate change'. Participation from a large number of U.S. and foreign institutions is expected. JGOFS investigators have begun a set of time-series

measurements and global surveys of a wide variety of biological, chemical and physical quantities, detailed process-oriented studies, satellite observations of ocean color and wind stress and modeling of the bio-geochemical processes. These experiments will generate data in amounts unprecedented in the biological and chemical communities; rapid and effortless exchange of these data will be important to the success of JGOFS. Since the mid 1980s, much of the marine science research effort in the United Kingdom has been focused into large scale collaborative projects involving public sector laboratories and university departments, termed Community Research Projects. Two of these, the Biogeochemical Ocean Flux Study (BOFS) and the North Sea Project incorporated large scale data collection to underpin multidisciplinary modeling efforts. The challenge of providing project data sets to support the science was met by a small team within the British Oceanographic Data Centre (BODC) operating as a topical data center. The role of the data center was to both work up the data from the ship's sensors and to combine these data with sample measurements into online databases. The working up of the data was achieved by a unique symbiosis between data center staff and project scientists. The project management, programming and data processing skills of the data center were combined with the oceanographic experience of the project communities to develop a system which has produced quality controlled, calibrated data sets from 49 research cruises in 3.5 years of operation. The data center resources required to achieve this were modest and far outweighed by the time liberated in the scientific community by the removal of the data processing burden. Two online project databases have been assembled containing a very high proportion of the data collected. As these are under the control of BODC their long term availability as part of the UK national data archive is assured. The success of the topical data center model for UK Community Research Project data management has been founded upon the strong working relationships forged between the data center and project scientists. These can only be established by frequent personal contact and hence the relatively small size of the UK has been a critical factor. However, projects covering a larger, even international scale could be successfully supported by a network of topical data centers managing online databases which are interconnected by object oriented distributed data management systems over wide area networks. In the 1920s, before the advent of echo sounders, fishery biologists were greatly concerned with assisting the fisherman to locate schools of pelagic fish. One of the approaches they developed was to relate the distribution of the planktonic food organisms to the presence of the schools of predators such as herring (Clupea harengus). The British planktologist, Alister Hardy, who had already carried out extensive studies on the feeding preferences of herring (Hardy, 1926a), initiated a program to examine the fishermen's contention that herring schools avoided 'green', i.e., phytoplankton-rich, water but could be correlated with high concentrations of zooplankton. This practical program was centered on the use of a specially developed instrument, the 'Plankton Indicator', designed to be used by the fisherman to assist in the search for suitable waters. It had limited success in its main aim but, as a collecting device, it embodied several profoundly important features. It was a simple instrument which was robust enough to be deployed and recovered by the crew of commercial vessels (in this case fishing vessels) while they were underway. The Indicator however, was no more than a high speed net which integrated the plankton over the area of sampling, but Hardy had also become interested in describing the patchiness of planktonic populations. He thus developed the Continuous Plankton Recorder (CPR) where he substituted the fixed filter screen of the Indicator by a continually moving length of silk mesh. The screen traversed at constant speed across the path of the incoming water and the trapped organisms were retained in place by sandwiching beneath an additional second mesh screen. Thus, knowing the speed of the towing vessel and the shooting and hauling positions, the spatial patterns of the plankton could be determined. Hardy took the first CPR to the Antarctic where he used it in the Southern Atlantic (Hardy, 1926b) and later deployed it in the North Sea to make some of the earliest contiguous records of plankton patchiness. Bermuda is the site of two ocean time-series programs. At Hydrostation S, the ongoing biweekly profiles of temperature, salinity and oxygen now span 37 years. This is one of the longest open-ocean time-series data sets and provides a view of decadal scale variability in ocean processes. In 1988, the U.S. JGOFS Bermuda Atlantic Time-series Study began a wide range of measurements at a frequency of 14-18 cruises each year to understand temporal variability in ocean biogeochemistry. On each cruise, the data range from chemical analyses of discrete water samples to data from electronic packages of hydrographic and optics sensors. In addition, a range of biological and geochemical rate measurements are conducted that integrate over time-periods of minutes to days. This sampling strategy yields a reasonable resolution of the major seasonal patterns and of decadal scale variability. The Sargasso Sea also has a variety of episodic production events on scales of days to weeks and these are only poorly resolved. In addition, there is a substantial amount of mesoscale variability in this region and some of the perceived temporal patterns are caused by the intersection of the biweekly sampling with the natural spatial variability. In the Bermuda time-series programs, we have added a series of additional cruises to begin to assess these other sources of variation and their impacts on the interpretation of the main time-series record. However, the adequate resolution of higher frequency temporal patterns will probably require the introduction of new sampling strategies and some emerging technologies such as biogeochemical moorings and autonomous underwater vehicles. The processes controlling the flux of carbon in the upper ocean have dynamic ranges in space and time of at least nine orders of magnitude. These processes depend on a broad suite of inter-related biogeochemical, bio-optical, and physical variables. These variables should be sampled on scales matching the relevant phenomena. Traditional ship-based sampling, while critical for detailed and more comprehensive observations, can span only limited portions of these ranges because of logistical and financial constraints. Further, remote observations from satellite platforms enable broad horizontal coverage which is restricted to the upper few meters of the ocean. For these main reasons, automated subsurface measurement systems are important for the fulfillment of research goals related to the regional and global estimation and modeling of time varying biogeochemical fluxes. Within the past few years, new sensors and systems capable of autonomously measuring several of the critical variables have been

developed. The platforms for deploying these systems now include moorings and drifters and it is likely that autonomous underwater vehicles (AUV's) will become available for use in the future. Each of these platforms satisfies particular sampling needs and can be used to complement both shipboard and satellite observations. In the present review, (1) sampling considerations will be summarized, (2) examples of data obtained from some of the existing automated in situ sampling systems will be highlighted, (3) future sensors and systems will be discussed, (4) data management issues for present and future automated systems will be considered, and (5) the status of near real-time data telemetry will be outlined. Finally, we wish to make it clear at the outset that the perspectives presented here are those of the authors and are not intended to represent those of the United States JGOFS program, the International JGOFS program, NOAA's C&GC program, or other global ocean programs. Listening to the case studies that were presented it became quite evident that the best data management systems were the ones where data managers and research scientists worked as a team developed in the early stages of project planning. Examples that were given included WOCE Data Assembly Centres e.g., Drifters, the Global Temperature Salinity Pilot Project (GTSPP) collaboration with Joint Analyses Centres in the U.S. and Australia, and JGOFS/BOFS development of Topical Centres. While each of these has some elements unique to the project, each had brought together 'teams' of Principal Investigators (PI's) and data management experts at an early stage of project development. Conversely, projects which had considered data management as a totally separate activity with lower priority often failed to provide the service required to meet scientific objectives. Therefore, the following actions should be brought to the attention of relevant groups within the IOC and other international organizations: (1) Publicize, at the national and international level, underway data/scientist collaborations that may be used as models in planning for the future. (2) Reduce adversarial situations where data managers and scientists appear to be in competition. (3) Colocation and other forms of collaboration often results in very high quality data sets and more timely data submission. Improved timeliness of data submissions was a common theme throughout the workshop and must be considered an important element in all future plans. Improvements in timely submission of data were noted. In order to continue this trend the advantages of timely submission of data must be stressed to those planning new ocean science projects. Considering the objectives of the Ocean Data Climate Workshop this week and trying to select a related, but not too technical subject, I decided to look at the services needed for ocean clients. I thought that it would make an interesting theme to consider how the acceptance of international ocean services is progressing over the years. Or is it? Are we closer to having a global observing system than we were twenty years ago? If so, what has changed between then and now? What is different between the efforts of twenty years or so ago to get the Integrated Global Ocean Stations System (IGOSS) off the ground and the present attempts to establish the Global Ocean Observing System (GOOS)? Is there a window of opportunity now that didn't exist then? If it doesn't happen now, a legitimate question could well be asked.... Will it ever happen? At least on historical topics I am on firm ground, having been attending IOC meetings for many years, in fact, it was in 1970 that I attended my first IGOSS meeting and a couple of years later I started what was to become regular attendances at the IOC Governing Body sessions. Despite the numbing effect of sitting through IOC related meetings for a total of what must add up to two or three years, I can still defend the IOC as an essential intergovernmental body for the oceans. One can accept the value of medicine, but one doesn't have to enjoy the taste. Author

In addition to the discussions, Ocean Climate Data Workshop hosts gave participants an opportunity to hear about, see, and test for themselves some of the latest computer tools now available for those studying climate change and the oceans. Six speakers described computer systems and their functions. The introductory talks were followed by demonstrations to small groups of participants and some opportunities for participants to get hands-on experience. After this familiarization period, attendees were invited to return during the course of the Workshop and have one-on-one discussions and further hands-on experience with these systems. Brief summaries or abstracts of introductory presentations are addressed. Author

The European International Space Year conference was held with the specific theme of the practical use of space derived information for environmental research and monitoring and resource management. This main theme, 'Mission to Planet Earth,' was maintained, but it was recognized that other fields needed to be equally addressed to provide a balanced view on space activities. Space sciences, space navigation and communications, and manned space activities were also represented. The present volume consists of papers addressing the following topics: general topics, methodology, and meteorology; geology, environment, and land cover; disaster monitoring; operational status of remote sensing; coastal zones and inland water; forestry; agriculture; and instrumentation and systems. For individual titles, see N93-24776 through N93-24874.

USE OF AIRBORNE IMAGING SPECTROMETRY TO THE DEFINITION OF OPTIMISED SPECIFICATIONS FOR LAND APPLICATIONS WITH FUTURE SPACEBORNE IMAGING SPECTROMETERS

J. Bodechtel, S. Sommer, H. Bach, and W. Mauser *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 405-409 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Airborne and ground data obtained from different test sites in Europe are used for a comparative analysis of the spectral signatures of various land surfaces (vegetation, bare soils and rocks, and mixed soil/rock vegetation) as seen from different imaging spectrometers. Recent experience with airborne imaging spectrometers has demonstrated the advantages of narrowband sensors over broadband scanners such as LANDSAT TM for characterizing the nature and physical status of typical land surfaces. Information on key spectral features associated with various land surfaces can be obtained from the data of airborne imaging spectrometers, which can be used to simulate spaceborne high spectral resolution data and to assess their information content if comprehensive underpinning is provided by ground data. The calibration of data acquired with NASA DC-8 SAR (Synthetic Aperture Radar) is reported. Signatures and polarimetric features of terrain classes are extracted and explained with respect to frequency and incidence angle dependence. Applications of polarimetric contrast enhancement, separation, and classification of object classes are demonstrated, and an approach to assess and optimize feature information is proposed. Summarizing the various topics of remote sensing applications and the analysis results discussed, the superiority of polarimetric SAR sensors with multifrequency capability against conventional SAR systems is demonstrated. THE SCOPE OF DLR'S SAR CALIBRATION PROGRAM

H. Kietzmann *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 419-421 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The preparation of SAR (Synthetic Aperture Radar) calibration experiments concerning the SAR spaceborne remote sensing missions X-SAR/SIR-C, ERS-1, JERS-1, and PRIRODA, is reported. These SAR missions will deliver a large number of different SAR image products which are of special interest for various kinds of scientific disciplines. For an optimum use of these products, the best possible calibration is necessary. Therefore, a series of calibration experiments approved by the mission relevant review boards is being performed. To perform such a calibration, the main error sources and the error contributions of essential system parts like sensor, antenna, and external calibration references were investigated separately. For obtaining the experiment objectives, a large number of high precision trihedral and dihedral corner reflectors and especially designed calibration receivers and active radar calibrators are available. ESA

REMOTE SENSED SPECTRAL SIGNATURES CLASSIFICATION AND RECOGNITION BY NEURAL NETWORKS: AN APPROACH TO UNSUPERVISED TECHNIQUES

L. Alberotanza and M. Pavanati (Venice Univ., Italy.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 423-428 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The use of an adaptive resonance neural networks scheme to analyze multispectral remotely sensed images on a lagoon environment and coastal waters is reported. An attempt was made to develop a substantially unsupervised classifier, obtaining an algorithm capable of independently organizing the learning stage on the basis of the same data under analysis. Information is requested from the external operator to limit the number of classes to be recognized. It is not necessary to use models for samples of spectral signature. The experience acquired can be transferred to successive recognitions. The method makes use of the separation of color information from that of the intensity of the analyzed radiation, and derives from radiometric corrections and calibrations. ESA

CORRELATION BETWEEN NDVI VALUES DERIVED FROM NOAA AVHRR HRPT DATA AND GROUND MEASUREMENTS OF PRECIPITATION IN THE EFEDA STUDY AREA (SPAIN)

Jose F. Moreno, E. Lopez-Baeza, Joaquin Melia, D. Segarra, and J. Tamayo (National Inst. of Meteorology, Valencia, Spain.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 429-434 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Research within the context of the EFEDA (ECHIVAL Field Experiment on a Desertification threatened Area) experiment, a European contribution to the International Geosphere-Biosphere Program (IGBP), is presented. The study area is located in the Spanish region of Castilla-La Mancha, and the main field campaign took place in Jun. 1991. The study is intended to characterize the conditions under which the field experiment was carried out, within the framework of a retrospective climatological study. The analysis of the correlation between NDVI and precipitation was addressed in two different ways: a point to point approach between the precipitation value of each station and the averaged value of NDVI (derived from AVHRR (Advanced Very High Resolution Radiometer) data) over an area of 25 sq km around the location of the station; and an image to image correlation approach between the NDVI map derived from AVHRR data and a precipitation map derived from the network of meteorological stations. The NDVI precipitation correlation shows a significant dependence on the spatial scale. Only at coarse scales is it possible to understand such correlation because of the complexity of the hydrological structure of the EFEDA study area. ESA

N93-24781# VERTIC, London (England).

VERIFICATION OF A CLIMATE CONVENTION: ROLE AND LIMITATIONS OF A SPACE BASED REMOTE SENSING SYSTEM

J. F. Lanchbery, W. Fischer (Kernforschungszentrum G.m.b.H., Karlsruhe, Germany.), R. Katscher (Kernforschungszentrum G.m.b.H., Karlsruhe, Germany.), and G. Stein (Kernforschungszentrum G.m.b.H., Karlsruhe,

Germany.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 435-447 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A03/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Techniques currently under discussion for verifying compliance with an international climate convention are discussed. The protocols of such a system are likely to include space based remote sensing systems. Present and potential verification sectors for such systems and the likely technical demands of the verification system user are indicated. Space based remote sensors currently offer the prospect of being used to monitor changes in vegetation on the Earth's surface and could thus be used as tools to verify compliance with a forest protocol and possible land use or agriculture agreements. The capabilities and limitations of currently available remote sensing techniques in this type of application are discussed and some of the technical requirements of remote sensors in other areas likely to need verifying under a climate convention are explored. ANOVA METHOD TO ESTIMATE VEGETATION INDICES SENSITIVITY ASSESSING NITROGEN FERTILIZING INFLUENCE ON SPECTRAL REFLECTANCE COEFFICIENTS

Tony K. Yanev, Rumiana H. Kancheva, and Valentina S. Boycheva *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 449-451 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The sensitivity of Vegetation Indices (VI) to changes in the spectral reflectance data, by which the VI values were calculated, was estimated by the ANOVA (variance analysis) method. Greenhouse evidence for Spring barley, which was fertilized by nitrogen and grown from emergence to ripeness, was processed. The ANOVA method is a model free method and provides the possibility of a comparative analysis of the VI sensitivity to be performed without the requirement of the knowledge of model correlationships between VI and bioparameters. ESA

SPECTRAL REMOTE SENSING OF ANOMALOUS MINERALOGY INDUCED BY HYDROCARBON MIGRATION AND URANIUM MINERALIZATION, SAN RAFAEL SWELL, UTAH, USA

Hayati Koyuncu (Hacettepe Univ., Ankara, Turkey.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 455-460 Sponsored in part by Ministry of Education, Turkey, and Geological Survey, Denver, CO (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Landsat Thematic Mapper (TM) data were digitally processed, analyzed, and interpreted for iron oxide, carbonate, and hydroxyl bearing mineral anomalies associated with hydrocarbon induced alteration and/or uranium mineralization in the San Rafael Swell, Utah. Discrimination of these minerals or mineral assemblages was possible based on their absorption features (spectral properties) that fall within TM spectral passbands. For this purpose, band ratios were calculated and combined to produce a Color Ratio Composite (CRC) image on which altered rocks were characterized by color differences. The colors of the CRC were further analyzed and classified numerically by digitally transforming the CRC digital numbers into Munsell color coordinates (intensity, hue, and saturation). Subsequent field checks and laboratory spectral, X-ray diffraction, and microscopic analyses of rock samples were performed to determine alteration minerals and/or mineral assemblages, and to establish a mineralogic basis for the spectral anomalies (altered versus unaltered rock) observed on the images. The TM data discriminated limonitic rocks from nonlimonitic rocks, as well as clays and carbonates, although an unambiguous identification of which of these minerals was present could not be made and required field checking. SATELLITE REMOTE SENSING FOR ENVIRONMENTAL GEOLOGY: THE BANDUNG (WEST JAVA) EXPERIENCE

Dietrich Bannert, P. H. Silitonga (Directorate of Environmental Geology, Bandung, Indonesia.), and Michael Siebenhuener (German Environmental Geological Advisory Team, Bandung, Indonesia.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 461-464 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Experience in satellite remote sensing for environmental geology of greater Bandung in Java (Indonesia) is discussed. The details of the following are described: data collection, remote sensing, groundwater data, industrial minerals and rocks, soil data, and landslide inventory. Greater Bandung is rapidly expanding and poses great problems for the environment. The land is intensively used and future changes in land use will have to be carefully planned in order to minimize the risk of future environmental damage. The compilation of various data leads to a complete assessment of the natural and environmental potential of the area. SPOT image interpretation was among the most important data sources for actualization of the urban and land use map and for the evaluation and identification of environmental and engineering geological problems. ESA

N93-24785# Fernerkundungszentrum, Potsdam (Germany).

APPLICATION OF REMOTE SENSING DATA FOR THE INVESTIGATION OF ENVIRONMENTAL DEGRADATION SITES IN EAST GERMANY

Karl-Heinz Marek *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 465-469 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Environmental problems, specifically those brought about by anthropogenic change and degradation of landscapes--which is marked by the decreasing use of land for agricultural and forestry purposes and the increasing use of land for open coal mining, military bases, and waste sites--are addressed. The availability and practical use of remote sensing data from space for environmental monitoring and recycling of such suspected areas was demonstrated at damaged sites in the eastern part of Germany. The methodological approach of the assessment is based on deriving environmental indicators like land use pattern, thermal pattern, vegetation, and other indices from space-based remote sensing data. The multitemporal analysis and combination of these complex indicators allow recognition of the environmental processes. ESA

Aerial panchromatic and false color infrared photographs and thermal scanner images were the first sources of information to study environmental change in Poland since the beginning of the seventies. A full range of available satellite data (Landsat Multispectral Scanner and Thematic Mapper, SPOT, NOAA, and Soviet space photographs acquired by automatic satellites of the Cosmos series and manned space missions) are now in use. More than 200 research and application projects were completed during the sixteen years of activity of the Polish remote sensing center. These projects were connected with forest appraisal studies, agricultural studies (soil moisture, evapotranspiration, statistics), surveys on land use changes (including detailed studies of man induced transformation of the environment), and water and air pollution studies. The geographical information system SINUS, which is oriented to monitoring of the environment at regional level, was developed at the center. The Polish National Point of the GRID

program was established in 1991. Many projects are conducted within the Intercosmos program, and current participation is in establishing the PRIRODA project. Collaboration has also started with ESA and national space agencies in western Europe, and it is hoped that ERS-1 and other programs will be effective for environmental monitoring and studies in Poland. LAND COVER, AN ESSENTIAL COMPONENT OF THE CORINE INFORMATION SYSTEM ON THE ENVIRONMENT: GIS IMPLICATIONS

M.-H. Cornaert and J. Maes *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 473-481 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Aspects of the Commission of the European Communities' CORINE (Coordination of Information on the Environment) program are presented. The results of this program will constitute an essential input to the setting up of the European Environment Agency. The results are of three types: European expert networks to work together at common targets; common methods and nomenclatures; and a series of thematic data bases integrated in the CORINE Geographical Information System (GIS). The main GIS data sets concern biotopes (sites important for nature conservation), soil quality and erosion risk, coastal erosion risk, emissions into the air, land cover as well as geographic and socio-economic background information. The use of these data in a GIS environment, linked to data base management and statistical packages, provides a powerful tool for the generation of information for environment and physical planning policies, at Community, national and regional levels. The results of a project concerning the use of remote sensing information in environmental protection are presented. This project is closely connected with the CORINE (Coordination of Information in the Environment) land cover project, whose capabilities it extends into the regional sphere by using 1:50,000 scale and greater resolution of input data. Much of the obtained information is directly applicable in regional planning and control. Image analysis and classification were applied on Landsat Thematic Mapper data and SPOT images covering the area of two districts. The land units containing risk factors were covered by the aerial photographs, time series of photos, or videotape data. ESA

LAND COVER MONITORING IN THE NETHERLANDS APPLYING SATELLITE REMOTE SENSING

G. J. A. Nieuwenhuis, J. D. vanAmsterdam, C. G. J. Schotten, and H. A. M. Thunnissen *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 489-495 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The production of a complete digital land cover database of the Netherlands with Landsat TM (Thematic Mapper) images, mainly acquired in the Summer of 1986, is reported. For several reasons only one image was applied during the growing season, hence, less accurate results were obtained for specific land cover classes. On a relatively global scale (1:100,000 and smaller), the available database can be applied on a national level, while derived statistics are applicable at a regional level, especially for agricultural areas. Methods were developed to improve the classification results based on a multitemporal analysis of satellite data and on integration with ancillary data such as digitized topographical maps and soil maps. The developed method was tested for a province in the southern part of the Netherlands. Since, in humid regions such as the Netherlands, data acquisition in the short wave range of the electromagnetic spectrum may cause problems, the application of ERS-1 radar images, in addition to images taken in the short wave range, was investigated. The first results were promising. ESA

MONITORING AND ANALYSIS OF URBAN TRENDS USING MULTITEMPORAL SATELLITE-IMAGERY (CASE-STUDY: GREATER CAIRO)

Marion Czeranka *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 497-501 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The use of a LANDSAT Thematic Mapper and SPOT data to examine the metropolitan area of Greater Cairo (Egypt), in the context of serious problems caused by the rapid increase in population and the resulting dynamic development, is reported. The monitored period of 10 years required different sensor data for the time points in 1979, 1982, and 1988. Consequently, a method was developed using a combination of unsupervised classification, image interpretation, and overlay techniques to perform a post classification comparison. The resulting land use/land cover changes provide current information about regional development patterns. Thus, it is possible to point out some differences in development concerning trends on arable land and on desert land, as well as for different political units within the conurbation. This feasibility study shows that, especially for large urban areas with uncontrolled development, monitoring within multitemporal satellite data is, indeed, appropriate to meet planners needs if there is a lack of fundamental and up to date data. DETECTION OF LAND USE/LAND COVER CHANGES USING REMOTE SENSING AND GIS IN VIETNAM

Pham Trung Luong *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 503-507 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A study to develop a procedure for application of remote sensing and GIS (Geographic Information System) to analysis of land use/land cover changes is described. The study was carried out for coastal areas of the Red and Mekong river plains, where the land use/land cover is most changed according to human activities. The multitemporal land use/land cover maps produced from visual interpretation of different sensing data were digitized and integrated into GIS. The land use/land over were analyzed by a GIS overlay technique. ESA

GEOLOGIC AND HYDROGEOLOGIC MAPPING OF ICELAND WITH MULTISENSOR DATA (JERS-1, ERS-1, SPOT, LANDSAT AND SEASAT)

U. Muenzer and C. Boehm *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 509-511 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Tasks for a program of geological, hydrogeological petrographic, tectonic, and environmental research on Iceland, to be carried out from 1992-1994, are outlined. A major objective is the compilation and interpretation of maps based on multisensor and multitemporal remote sensing data obtained from JERS-1 (optical sensors and SAR (Synthetic Aperture Radar)), ERS-1 (SAR), Landsat (multispectral scanner and Thematic Mapper), SPOT High Resolution Visible (HRV), and SEASAT (SAR). Spectrometric in situ measurements and laboratory analyses are to be made as well. Results

are expected to greatly facilitate the identification and interpretation of terrain features to lead to greater detail and accuracy in cartographic work. ESA

DETERMINATION OF ENVIRONMENTAL DYNAMICS USING NOAA SATELLITE DATA AND A WATER BALANCE MODEL FOR THE MEDITERRANEAN LANDSCAPE

P. Peroni, A. DEpifanio, and C. Martellacci *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 519-523 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The analysis of vegetation condition during the critical season in the Mediterranean area (Summer period) was performed. The analysis was carried out with a synthetic approach to the study of the vegetation dynamics in terms of the physiological state, which is a function of the main components: vegetation cover, water availability, and photosynthetic activity. A synthetic stress index was defined from the integration of static (land use map) and dynamic information coming from NOAA AVHRR (Advanced Very High Reolution Radiometer) satellite data and from the output of the Thornthwaite water balance model. Applications to the island of Sardinia and preliminary results for the year 1989 are presented. Results suggest that an integrated approach to a dynamic phenomenon can represent a useful instrument in regional control planning for forest fire prevention. ESA

AGROCLIMATOLOGICAL ZONATION BY AVHRR DATA FOR VEGETATION MONITORING

R. Benedetti, P. Rossini, and M. Sernicola *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 525-530 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A study which aims firstly, to define areas with homogeneous time NDVI (Normalized Difference Vegetation Index) profile characterized by a similar vegetation composition and timing, and then to select and identify, within these zones, areas with different photosynthetic potential and productivity is presented. Advanced Very High Resolution Radiometer (AVHRR) images from NOAA 9 and 11 were used. The method chosen is an unsupervised classification of each single pixel NDVI profile, with a posteriori interpretation of each class obtained. The timeframe chosen is the four year span between 1986 and 1989, and the study area considered is the Mediterranean region centered on Italy. Thirty-nine (39) homogeneous areas with different photosynthetic potential and timing are produced and grouped in 17 main typologies of land cover. ESA

A KNOWLEDGE-BASED APPROACH TO WASTE DISPOSAL SITES DETECTION THROUGH INTEGRATION OF LANDSAT-TM IMAGERY AND GEOGRAPHICAL CONTEXT INFORMATION

R. Loguercio-Polosa, C. Piccinni, N. Sciacovelli, and A. M. Tonelli *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 531-534 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A satellite image interpretation methodology using a knowledge based approach is presented. The methodology integrates traditional image processing techniques and knowledge of spectral, spatial, and contextual properties. The method is intended for use on Landsat TM (Thematic Mapper) imagery in processes of waste disposal site detection. The integration model used is based on the Dempster Shafer theory of evidence which offers a suitable data fusion and uncertainty handling framework. The knowledge necessary to drive the detection process is derived from the results of spectral and spatial analyses performed on the training Landsat TM scene and from other information relating to specific properties and features of dump sites. USE OF REMOTE SENSING AND GIS FOR THE ENVIRONMENTAL PLANNING PROPOSAL OF THE SARNO RIVER VALLEY (CAMPANIA, SOUTHERN ITALY) Final Report

F. Jemma *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 535-539 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The final report of a multidisciplinary research project into the definition and experimentation, in a pilot area, of an environmental planning methodology is presented. The methodology is thought of as a continuous process of territorial management coherent with the hydrogeological reclamation of the study area and the reduction to the miniumum level of the water pollution hazard. The environmental water planning methodology together with the contribution that Geographic Information System (GIS) and satellite remote sensing give for the land use data collection, analysis, processing, and management, are reported and discussed. COMPLEX INVESTIGATION OF A SYSTEM INDUSTRIAL SITE-ENVIRONMENT USING REMOTE SENSING AND LANDSCAPE-GEOCHEMICAL METHODS

H. Spiridonov, E. Roumenina, and L. Milenova *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 541-545 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A prerequisite for the successful development of a complex of measures for protection of the environment and the rational exploration of natural resources in industrially loaded landscapes is the investigation of qualitative and quantitative characteristics of pollutants, emitted into environment. The basic results are presented from the complex application of remote sensing and landscape-geochemical methods in one region within the territory of Bulgaria. Thematic and landscape geochemical and water pollution data maps are drawn using aero and space images. The character of industrial emission is investigated. The accumulation of industrial emissions in soils and vegetation is followed for each separate elementary landscape. The results obtained from the complex investigation work on the territory of the industrial site environment system are used in determining the points for operative pollution control of elementary landscapes in areas of industrial impact for the purpose of environmental status, assessment, and prognostication. ARCHAEOLOGICAL, HISTORICAL AND GEOELECTRICAL DATA AS GROUND TRUTH FOR LANDSAT TM IMAGERY APPLICATION TO COASTAL PLAIN EVOLUTION STUDIES

V. Alessandro, F. Maselli, M. Pieri (REDAT, Rome, Italy.), E. Pranzini (Florence Univ., Italy.), and V. Zichella (Florence Univ., Italy.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 547-551 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Some examples of the integration of archaeological, historical, and geoelectrical data with Thematic Mapper (TM) remotely sensed data are presented. The different case studies were drawn from research carried out on the Tuscan coastal plains (Italy) where this procedure allowed reliable results to be obtained. Archaeological and historical data have both aided the interpretation of remotely sensed images and directed image processing towards the highlighting of specific features whose existence they suggest. Geoelectrical soundings have solved some problems arising from the disagreement between remotely sensed data and archaeological and/or historical ones. The various types of data are concluded to serve as ground truth in remote sensing when this is applied to the study of the geomorphological evolution of coastal plains. Archaeological findings as well as literary sources and old maps give detailed information that can be used to date forms and processes. Vertical geoelectrical soundings can sometimes explain anomalous spectral behaviors of the soil surface and help in relating image interpretation with 'remote' data. ESA

THE PHOTOINTERPRETATION OF THE AREA TAKEN OVER FROM AGRICULTURE BY INTENSE URBANIZATION AT VILLABATE (PALERMO, ITALY)

Salvatore Raimondi *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 553-556 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A study on area taken away from agricultural activity in the territory of the commune of Villabate (Palermo, Sicily) between 1968 and 1987 by photointerpretation is reported. The results showed up the effects of next few years urban expansion on the studied areas and damages on the soils with high agronomic potentiality. The wise choice of an area, based on pedological studies and interpretations of the latter, could save soils with high productive capacities for agriculture, while those with lower potentiality could be used for nonagricultural purposes. ESA

DEMONSTRATION OF SEASONAL CHANGES IN THE TERRITORY OF FINLAND USING MULTITEMPORAL NOAA-AVHRR DATA

Kaj Andersson *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 557-558 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Work to demonstrate the possibilities of remote sensing in monitoring the Earth environment is reported. An image display system was developed for displaying sets of consecutive remote sensing images on a powerful UNIX workstation. The first image set gave the impression that the viewer was approaching the Earth from outer space. In the uppermost level the whole Earth globe could be seen and the following images showed the views from Meteosat, NOAA, Landsat MSS (Multispectral Scanner), Landsat TM (Thematic Mapper), SPOT and scanned aircraft images. The lowest level image was constructed from different sets of geophysical data and it showed the 'scene' from below the surface of the Earth. The second image set consisted of partly cloud free NOAA AVHRR satellite images acquired over Finland in 1991 and were displayed in a sequence to demonstrate the seasonal changes in the nature. ESA

THE USE OF REMOTE SENSING AND GIS FOR THE ASSESSMENT OF ENVIRONMENTAL DEGRADATION CAUSED BY FIRES, APPLIED UPON SOUTH-EUBOIA (CENTRAL GREECE)

Beata Maria DeVliegher *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 559-564 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A study to map the risk of environmental degradation by fires using a multisource and multitemporal data set and a combined and integrated research using the ILWIS (Integrated Land and Watershed Information System) is presented. Five thematic maps together with the localization map of the fires during 1981-1989 are stored in the GIS (Geographic Information System). Additional data about the area, date, owner and type of vegetation were also imported. The factors form part of a hierarchical system indicating the influence: vegetation, altitude/aspects, slope/accessibility. In correspondence with the rank, a weight is given; a score is assigned for each category according to the risk. The combination of the single risk for each factor gives the fire risk which is ranked into four classes (none to severe). ESA

LITHOLOGIC MAPPING WITH LANDSAT THEMATIC MAPPER GUIDED BY LABORATORY SPECTRAL MEASUREMENTS, AIR, NIGER (AFRICA)

P. Trefois and C. Volon *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 565-570 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The identification of different lithologies in the Air Massif (Niger, Africa) from satellite data is based on the knowledge of the spectral signatures from minerals and rocks collected during several field surveys. This spectral study is thus performed by a deterministic type of image processing. High resolution spectral reflectance signatures of these samples were measured in the laboratory and interpreted. The link with the remotely sensed data is established through a calibration procedure, using the 5S atmospheric correction model. After calibrating TM (Thematic Mapper) data to reflectance factors, a ratio technique was adopted in order to minimize the effects of topography. Color composite of a combination of TM bands ratios (5/7, 5/1, (3+5)/4; Crippen, 1988), is displayed and interpreted to emphasize the spectral features related to hydroxil or carbonate band absorptions, and to the presence of ferrous and ferric ions. ESA

ALTERNATIVE STRATEGIES FOR THE USE OF SATELLITE DATA ANALYSIS SYSTEMS FOR HAZARD MONITORING AND DISASTER MITIGATION
Eric C. Barrett and Michael J. Beaumont *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 581-586 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A feasibility study to identify and evaluate comparatively the range of options for a satellite based snow monitoring operation in the United Kingdom, to improve near real time intelligence on snow area, type, depth and water equivalence, dependent advisories on flood potential and peaks of river water acidity, and the organization of disaster mitigation responses, is presented. The arguments and conclusions arrived at through this study are reviewed and compared with those encountered in Pakistan, a developing country, for which a more broadly based satellite environmental monitoring system was designed. The parameters already involved in this case include rainfall and vegetation productivity in addition to snow, and others considered for future incorporation in the system include temperatures at or near the ground, fires, and intense storms (both mesoscale, for example severe convective storms, and synoptic scale, for example tropical cyclones). Key factors identified as affecting the choice of satellite system for such operational uses in different types of countries are reviewed and discussed. It is concluded that quite different satellite environmental monitoring infrastructural strategies might be necessary in countries in different stages of development. ESA

SATELLITE BORNE REMOTE SENSING DATA: A TOOL FOR NATURAL DISASTER REDUCTION
F. Jaskolla and U. Lohr *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 587-590 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The recently available ERS-1 data offers for the first time the opening up of new fields of application due to their unique capability to provide information independent of weather or illumination conditions. Although the fact that ERS-1 is not an operational system providing environmental data, it can be demonstrated, that the phenomena to be measurable by ERS-1 can be designated as of utmost significance for the task in mind. In particular, the relatively simple detectability of flooded areas or the differentiability of areas affected by volcanic eruptions underline the generally high potential of this type of data. ESA

APPLICATION OF MULTITEMPORAL LANDSAT-MSS AND -TM DATA FOR THE DEVELOPMENT OF AN INUNDATION-RISK-MAP
H. Mehl and K. Hiller (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 591-594 Sponsored by BMFT (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Investigation carried out in the northwest of the province Buenos Aires (Argentina) to assess temporal and spatial surface changes of inundated areas with Landsat data (MSS (Multispectral Scanner), TM (Thematic Mapper)) are reported. For preparation of an inundation risk map, different approaches involving both simple image processing techniques and more sophisticated IHS (Intensity, Hue, Saturation) processing procedures were analyzed. The use of ratios gave suitable results for the extraction of water masks and their transformation into a map meeting cartographical standards. However, the procedure leading to the final map is very cost intensive. Therefore, a different multitemporal IHS approach was realized. Based on the multitemporal response of the principle components and the suitable use of an IHS transformation a new concept for the derivation of a computer based multitemporal product similar to a conventional risk map is demonstrated. ESA

SUSTAINABLE REMOTE SENSING: A MAJOR IMPROVEMENT FOR REALTIME RESOURCE MANAGEMENT AND DISASTER EARLY WARNING IN DEVELOPING COUNTRIES
J. B. Williams, J. Stephenson (Bradford Univ., England.), G. DSouza (Cranfield Inst. of Tech., Bedford, England.), and J. R. Milford (Reading Univ., England.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 595-598 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

To become sustainable and realize their potential for environmental monitoring in most developing countries, remote sensing techniques must be practical and be integrated into existing operational activities with minimal running costs. A program of technology transfer starting with direct Meteosat reception, continuing with NOAA, and leading on to higher resolution satellite applications appears to constitute a pragmatic and sustainable approach for even the poorest countries. Experience gained from working with a dozen operational low cost satellite receivers in developing countries is summarized. ESA

The demands by the current and planned utilization of remote sensing spacecraft in disaster management for facilities and services able to provide products characterized by fast delivery from acquisition, optimum source selection and integration of several data into a metadata, is addressed. This demand imposes on the existing space related infrastructure functional and performance requirements to build up an integrated system. Research to identify, detail, and assign to relevant entities the upgrading requirements, taking into account what already exists in terms of spacecrafts (and related payloads) and of ground infrastructure, is reported. This is performed by analyzing the interfaces of the regional operations center with the space related facilities (payload coordination center, user centers, processing and archiving facilities, acquisition stations). A key aspect addressed in this context is the concept of metadata, with respect to its applicability within real time environment monitoring. ESA

THE USE OF SPOT DATA IN NATURAL DISASTER PREVENTION AND DAMAGE ASSESSMENT

J. C. Rivereau *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 611-613 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

SPOT can efficiently contribute to gather valuable information in disaster prevention and preparedness, damage assessment and disaster relief. In disaster prevention, risk analysis requires the compilation of information extracted from SPOT data: land use, infrastructures, topography and morphology (DEM (Digital Elevation Model)), hydrography, geology, soil types. The information is introduced into geographic information systems to establish hazard maps and risk potentialities. Vulnerability maps and contingency plans are thus derived by adding socio-economic factors. In case of disaster, the assessment of damage is vital to undertake relief measures and in the long term recovery and rehabilitation planning. In remote areas, SPOT images are often the only means of investigation if timely data can be obtained. For immediate disaster relief purposes, the use of SPOT is hampered by the difficulty to acquire good data in a very short period of time. But preparedness and disaster mitigation is strongly improved, in hazard prone areas, by establishing well in advance contingency studies to plan prevention means and measures. These documents are particularly useful to authorities to anticipate and plan energy actions according to actual situation and prevailing conditions. In the long term, SPOT data efficiently contribute to reconstruction and rehabilitation planning. ESA

The analysis of long term (no less than 10 to 30 years) aerial and space surveys for regional disaster monitoring in Russia is reported. Trend analysis of the aerospace monitoring of expansion of drift sands over the Kalmykia during 1954-1984 was used to predict full disaster degradation to 1992. More advanced technology based on a system approach using Markovian chains permitted forecasting of land desertification over the Amudarya delta to 2010. The verification of such a forecast revealed the error to be near 10 percent for 5 predicted years. Operations on models based on space supported dynamic models revealed the nonstability date of turning points which fell at the beginning of the 1970s. The format of the Dynamic EcoGeoInformation System was developed. ESA

A discussion on the global availability of observations for Earth weather and climate analyses is presented. Some examples of presently available spaceborne information for weather analyses are given. Concentration is only on the climate system from the troposphere down to the ground. Thermodynamic properties of the atmosphere and surface, atmospheric wind fields, and various relevant properties of the surface, are discussed. Other information for climate research, including radiation budget parameters and precipitation, are described. The lack of efficient and accurate methodologies to derive quantities describing the weather and Earth climate from satellite measurement is discussed. A recommendation for major investment in data analysis techniques and verification studies is made. ESA

REMOTE SENSING OF NON-RENEWABLE RESOURCES
J. Bodechtel *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 625-628 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The application objectives of remote sensing in geological and mineralogical sciences and the use of optical remote sensing are described. A comparison of the measurement capabilites of several scanner systems and the reflectivity properties of common surface minerals is given. Physical properties to be measured for nonrenewable resources are given. Advantages of microwave remote sensing are discussed. Existing remote sensing data sources are reviewed. User requirements for future satellite systems to extend the possibilities for the application of remote sensing data from space and to enable thematic evaluation on a scale of 1:50,000 to 1:100,000 are listed. The missions which these requirements call for are described. For nonrenewable resources, where phenomena can be analyzed directly only under certain optimum conditions using either multispectral or backscattered microwave information, a multisensor and multidata approach for identifying geology or pedology dependent indicators is essential. A payload combining an optical and a SAR (Synthetic Aperture Radar) sensor could provide the optimum operational capability, with the optical instrument yielding information about spectral behavior of the phenomena/indicators, and the radar giving the indispensable information on soil moisture, surface roughness, penetration and relief. Earth resources satellite data for geological research is discussed. Imagery, as well as spectral data are widely used in lithological and structural mapping, groundwater, mineral and hydrocarbon prospecting, and in environmental geological investigations. Spectroradiometry supports field and remote sensing work. The discussion focuses on the indipensable need of the human interpretation of satellite derived data. From the side of the interpreter it requires a sound education in his geological or geoscientific profession. From the side of the image processing, it requires an optimized image for the task at hand. Sensor development and higher spatial resolution of future satellites cannot replace the human interpretation of the acquired data. Better data, however, will improve the results of the human interpreter. ESA

For water management activities runoff is the most important component of the hydrological cycle, and remote sensing applications serve to increase knowledge of the temporal and spatial distribution of runoff from rain and snow. A review on the methods and models used to assess, monitor, and forecast hydrological relevant input, process, and output variables related to runoff, using various remote sensing systems, and on future possibilities with advanced sensor system is presented. These sensors penetrate clouds and overcome the weather and daylight dependence of optical remote sensing data. In particular ERS-1 and similar satellites will augment water management applications. POTENTIAL OPERATIONAL USE OF REMOTE SENSING FROM SPACE IN FORESTRY
G. Hildebrandt *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 639-646 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The different information requirements for remote sensing for forestry purposes are described and the question as to how far remote sensing from space can accomplish these requirements is answered. The main problems and methodic ways to overcome these (at least to a satisfying extent) are discussed. This includes visual analysis of object related enhanced color composites, optimized digital classification and hybrid approaches for the evaluation, the prestratification of the survey area, the role of ancillary and multitemporal data, atmospheric corrections, and so on. Guided by latest examples it is demonstrated that much more information can be reliably extracted from high resolution optical satellite imagery as it is often described. An assessment of the various remote sensing systems is given. ESA

REMOTE SENSING APPLIED TO AGRICULTURE STATE OF THE ART AND NEW TRENDS
Jean Meyer-Roux *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 647-649 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The monitoring of agriculture using specific remote sensing methodology, such as that developed in the pilot project MARS (Monitoring Agriculture by Remote Sensing) is discussed. Crop inventories and control, requirements, and trends, are discussed. Successful remote sensing techniques have used mainly cartographic visual products. For continuous monitoring, some stable techniques are being implemented. Real time applications are also being implemented at the level of the Commission of the European Community. There are still strong limitations such as cloud cover preventing image acquisition, but at the same time, data such as ERS-1 are appearing on the market which could overcome some of these problems. Methodologies are rapidly improving for large scale applications specially with the implementation of geographic information systems, whose techniques are quite complementary with remote sensing techniques. ESA

APPLICATIONS OF REMOTE SENSING FOR TIDAL WATERS, COASTAL AREAS AND INLAND WATERS
Roeland Allewijn *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 651-654 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A review of the main aquatic applications of spaceborne and airborne remote sensing techniques is given. Examples of the use of remote sensing for operational management of Dutch tidal waters, coastal areas and inland waters are presented. Some priorities for further research on applications of remote sensing for water management are given. In conclusion, for future remote sensing research two priorities can be defined: a strong emphasis on the applications of remote sensing for which the information needs of users should form the starting point; and the need for integration of data acquisition and analysis methods to solve the many environmental problems of the Earth. ESA

EUROPEAN APPLICATIONS OF SPACE-BORNE EARTH OBSERVATION FOR LAND COVER MAPPING
B. K. Wyatt and R. M. Fuller *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 655-659 Sponsored by British National Space Center; Dept. of the Environment, and Natural Environment Research Council (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Information on land surface cover and the manner with which this changes over time is needed for a variety of operational purposes. Data from spaceborne Earth observation offers a means of generating over extensive areas consistent and cost effective information in digital form, suitable for overlay with other geographically referenced data sets or for incoporation directly into numerical models. A number of recent initiatives in Europe are building on earlier experimental work in the use of digital remotely sensed imagery for land surface mapping and have resulted in large scale operational schemes for national and international applications. Such a program, currently in progress in the United Kingdom, with the objective of compiling a national digital map of land cover, is described. This land cover mapping project, based on the use of multitemporal Landsat Thematic Mapper imagery, is placed in its broader European context, with emphasis on the need to achieve intercompatibility between individual national initiatives and systems developed to service the requirements of the wider international community. The operational support of the Portuguese tuna and swordfish fisheries by provision with near real time products based on satellite measurements of sea surface temperature is reported. These products include charts with the location of thermal fronts and isotherms. Besides these operational activities, three research programs are being carried out to investigate the relations between tuna, swordfish and sardine aggregations and the distributions of oceanographic parameters as observed by the fishermen and using satellite data. A preliminary finding of this research is that sardines concentrate in moderately cool, relatively old upwelling waters, on the inner shelf off western Portugal. On the other hand, swordfish and tunas are preferentially found seaward of the semipermanent thermal front separating coastal waters from the warmer open ocean. ESA

The Japan Fisheries Information Service Center (JAFIC) makes satellite aided oceanographic condition charts with NOAA AVHRR (Advanced Very High Resolution Radiometer) data and sends these charts to fishing vessels at sea experimentally, because, it was shown that the NOAA AVHRR data were applicable to fishing ground forecasting. The indexes of fishing ground forecasting are as follows: the first index for monitoring fishing grounds is the most favorable temperature range of a target fish; the second index is an oceanographic environment such as warm/cold current, warm/cold eddy, front and intrusion of warm/cold water which is produced as a fisheries oceanographic chart by JAFIC; the third index will be ocean color which corresponds to distribution of phytoplanckton, that is pray condition, but which is not described here. JAFIC developed a discriminant prediction system of skipjack fishing ground formation using the NOAA AVHRR data (1982-1985). ESA

Remotely sensed data for oil pollution and water quality mapping over Augusta Bay in Sicily, Italy, since 1977, to investigate the usefulness of remote sensing techniques to the analysis of resource related problems, is reported. LANDSAT MSS (Multispectral Scanner) and TM (Thematic Mapper) data, along with MSS data, thermal infrared imagery, ultraviolet and infrared photography from lightplanes and helicopters are among the data acquired. Color coded imagery, showing oil pollution, distinguishing different types of it and calculating their extension were obtained. Color coded images, each depicting the distribution of a selected water quality parameter, were produced. ESA

The increased frequencies of toxic algal blooms in for example the North Sea and Adriatic Sea, which have caused severe problems to the human activities ranging from aquaculture to tourism are discussed. A multi-institutional research program, Norwegian Remote Sensing Spectrometry and Pollution (NORSMAP) between Norway and Canada was established to evaluate the potential of airborne imaging spectrometry for monitoring of such events in Norwegian waters. The Canadian Compact Airborne Spectrographic Imager (CASI) was used for a three week period in May 1989. Water masses covering a wide range of optical properties were analyzed and chlorophyll concentrations in the range from 0.8 to 5 micro-g/l were observed. A good large scale match between the in situ and airborne data are found, although the point to point comparisons are not convincing. ESA

THE EXTENT AND STATUS OF MANGROVES IN MOMBASA DISTRICT, KENYA: A CASE STUDY BASED ON REMOTE SENSING
P. O. Gang *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 693-698 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The distribution and present utilization of the mangroves are outlined. Mangrove vegetation communities are an important component of the Mombasa district environment. They form the only gazetted forest cover within the 275 sq km district. These forests are undergoing constant changes in response to human activities within the peri-urban environment. The study area has a variety of mangrove types including regeneration stages, dense old stands, and saltish dry banks almost devoid of halophytes. The study was carried out in the Mombasa mangroves based on a double sampling approach starting with SPOT multispectral satellite imagery followed by ground checks to provide information on species composition, density, and distribution of mangroves. Other forms of land uses around and within the mangroves were determined. This report outlines the distribution and present utilization of the mangroves. It is recommended that map products from SPOT data should be digitized using a geographic information system. This will keep record and allow for further overlay analysis with other resource maps and also for monitoring purposes. ESA

REMOTE SENSING OF COASTAL ZONE SABKHA DEPOSITS, GULF OF SIRT, LIBYA
Y. AlFasatwi, M. ElAlami, A. Sghir, and I. ElAradi (Bironi Remote Sensing Centre, Tripoli, Libya.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 699-702 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The mapping of the complex coastal sabkhas of the western Gulf of Sirt, Libya, from Landsat Thematic Mapper and SPOT data is reported. The main objectives are to examine the use of remote sensing data for coastal zone mapping, and to study the effect of sabkha sediments and depth of the ground water table in spectral reflectance of these sediments. Differences in spectral reflectances of different zones of sabkha in remote sensing images represents the differences in type of sediments and the effect of the soil wettness which is related to the thickness of capillary zone. The geomorphology and drainage system suggest that these sabkhas are more close to land sabkhas than marine sabkhas and the continental recharge is more likely. ESA

INHERENT OPTICAL PROPERTIES OF LAKES AS MEASURED BY LANDSAT 5 THEMATIC MAPPER
Waltraud Jahnen and Hartmut Grassl *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 703-708 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Lakes at different altitudes in different seasons are investigated by using the spectral measurements of all seven channels of Landsat 5 Thematic Mapper (TM). The calibration of these channels had to be improved. Then an atmospheric correction with help of a radiative transfer model was carried out to make the lake's signals comparable for different altitudes and seasons. Due to the different penetration of light into the water, the information content of each channel of the TM belongs to a different water depth. The channels in the middle infrared are used to investigate the existence and structure of surface films. ESA

EVALUATION OF NEARSHORE SUSPENDED SEDIMENT CONCENTRATION THROUGH LANDSAT TM DATA: FIRST RESULTS
Giuliana Profeti, Fabio Maselli (Consiglio Nazionale delle Ricerche, Florence, Italy.), and Enzo Pranzini *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 729-733 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An approach to evaluate the concentration of suspended sediment in coastal waters through Landsat Thematic Mapper data is reported. A modification of a standard methodology taking into account the influence of a homogeneous sea bottom in order to retrieve suspended sediment concentration is proposed. The contribution of the bottom is quantified and removed from the global reflected signal through an iterative procedure. This methodology was tested on two images of the Ombrone river mouth (southern Tuscany, Italy). The first results show its effectiveness in removing radiance coming from the sea bottom. Some problems concerning the applicability of this method to coastal water quality assessment are discussed. ESA

WORLD FOREST WATCH: A GLOBAL FOREST MONITORING TEST

Roberto PereiradaCunha and Jean Paul Malingreau (Joint Research Centre of the European Communities, Ispra, Italy.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 747-749 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The World Forest Watch is a joint project between the National Institute of Space Research of Brazil (INPE) and the Joint Research Center of the CEC (Commission of the European Communities) (Europe, JRC). The main objective of the project is to obtain both global and regional remote sensing satellite data in order to cover most parts of the tropical forest belt and some isolate temperate forest areas. The global forest coverage is currently being done by JRC (Italy) using NOAA AVHRR (Advanced Very High Resolution Radiometer) data at 1 km resolution. Embedded in the 1 km global coverage, regional high resolution data sets (for example LANDSAT) will be acquired for deforestation quantification. The regional projects are to be developed at 1:250,000 scale and will consist of wall to wall data sets. One example of this is the pan-Amazonia project which will cover the entire Amazonian forest for all countries. Examples and preliminary results of the pan-Amazonia deforestation project are presented. ESA

After the opening of the German/Czechoslovakian border, the government of the Czech Republic used the chance to declare the National Park of Sumava (Bohemian Forest) bordered to the National Park of Bavarian Forest. Tasks of landscape assessment in the region can be remarkably facilitated by methods of satellite remote sensing. The ability of Landsat TM (Thematic Mapper) evaluation could be demonstrated for the assessment of forest structure. In a subarea of 30 km by 30 km, covering the National Park of Bavarian Forest, a forest type classification and dead wood mapping was performed combining TM data and ancillary data. In another subarea, Landsat TM data of 1985, 1987, and 1989 were used on landscape change detection (appearance of coniferous forest parts) and also in studies for change explanation. ESA

APPLICATION OF PHOTOGRAPHIC REMOTE SENSING DATA FROM SPACE FOR INFORMATION ABOUT FORESTS

E. Pelz, K. Fritsche, and D. Hertel *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 757-760 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The investigation of the possibilities of the application of photographic satellite images for forestry purposes is reported. Radiometric evaluation of different image points or of the same object points in different images proved to be problematic without knowledge of the optical and sensitometric transmission parameters. With a KFA-1000 (Soviet camera) image, tests were carried out in the eastern Erzgebirge mountains and in the Tharandt forest (Germany). The analog classification of the Erzgebirge was much poorer because of the extreme damages of forests. Therefore a special classification is necessary. ESA

INTERPRETATION AND SEGMENTATION OF CHANGED FOREST STANDS FROM DIFFERENCE IMAGERY BASED ON REGRESSION FUNCTIONS

Haakan Olsson and Jan Ericsson *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 761-765 Sponsored in part by Swedish Board for Space Activities (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Difference imagery derived from both SPOT panchromatic and Landsat TM (Thematic Mapper) satellite data from 1989 and 1991 were generated by regression techniques. In a test with visual interpretation, all clearfelled areas and all soil scarifications were readily detected. About 1/3 of the cleaning cuttings and thinning cuttings could be easily detected. However, with prior knowledge about the approximate position some 2/3 of the cleaning and thinning cuttings could be delineated. All these changes turned out light in the difference imagery. A problem with difference imagery computed from regression functions was that also bright unchanged regions became too light in the difference imagery. Discriminant analysis of spectral mean values for automatically computed segments was also evaluated. Only Landsat TM data were used. The results suggest that automatic methods can aid the visual interpretation. ESA

THE ESA ISY INITIATIVES FOR FOREST INVENTORY IN EUROPE

K. Pseiner, F. Gampe, and B. Pfeiffer *In its* Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 767-768 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Forest inventory on a site, regional and global scale, based on remote sensing data, has become a key item of applied forestry and applications research. Scientific studies with high resolution data address the possibilities to establish forest inventories, the ways to distinguish between different forest categories (age, species, canopy density, etc.) and to monitor forest change and damage. Within the frame of the International Space Year (ISY) various field studies were performed or are underway to either show forest phenomena on a regional or even detailed site level (ISY Remote Sensing Forest Atlas) and to map forests on a Continental European Scale (Remote Sensing Forest Map for ISY). In order to develop operational methods for tropical forest monitoring a feasible low cost approach was used and evaluated with promising results. Digital satellite imagery is digitally coregistered and enhanced to produce color hardcopies. These are visually interpreted and area cover classes are manually delineated. An adopted point sampling design is used to estimate area cover. Using time coincident reference data the interpretation accuracy is evaluated and the area estimates calibrated. The methodology was tested and evaluated for the Chiang Rai province in northern Thailand. Landsat imagery from the same season of 1977, 1984, and 1990 was used. ESA

ASSESSMENT OF STORM DAMAGE IN FORESTS USING SPOT IMAGERY

Marc M. Leysen, Boudewijn P. DeRoover, Roland E. Goossens, and Robert

R. DeWulf *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 773-777 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The possibilities of assessing the impact of storms on forests by satellite remote sensing are evaluated. Two main objectives are put forward: the location of the damaged zones and the establishment of a quantitative relation between timber volume losses and spectral changes. Different modes, acquisition dates, and change detection techniques are compared. The change detection method elaborated is based on the combination of two coregistered panchromatic images, together with their difference image, on a color composite. Supervised minimum distance classification of this composite image results in accurate delineation of seriously damaged areas. Quantitative parameters of the spectral change of the forest stands, extracted from the difference image by averaging and level slicing, are regressed against the field data. Results indicate that the extraction of reliable information on storm damage from satellite imagery is restricted to stands where severe damage occurs, that is, where groups of trees were thrown. MAPPING OF WINDFALL DAMAGE IN THE HUNSRUECK PLATEAU WITH LANDSAT TM-DATA
Johannes Wieczorek *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 779-782 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Using data from the Landsat 5 TM (Thematic Mapper), a mapping of windfall areas in the region of the eastern, Hunsrueck plateau (Germany) is carried out. The first step is to make a general exposition of the usefulness of geographical information systems. Subsequently, it is found by classifying the data that the species most affected is spruce (Picea abies) grown in monocultures. By correlating these results with digitized soil data, it is possible to identify the static wet soils which, in combination with flat rooting spruce, show the highest potential for windfall damage. A prediction of potentially endangered areas can be made. ESA

THE USE OF POLARIMETRIC RADAR REMOTE SENSING DATA FOR APPLICATION IN FORESTRY
B. Koch, B. Foerster, and U. Ammer *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 789-793 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Investigations on airborne polarimetric radar remote sensing data were carried out to evaluate its use for the discrimination of forest classes. Signature analysis was carried out in reference to different orientation angles. The results showed that P band is most effective to differentiate between forests and agriculture land. Within the forest classes deciduous, pine, and spruce stands were separated in certain bands and for certain orientation angles. ESA

FOREST DECLINE MONITORING USING LANDSAT TM, DIGITAL STAND DATA AND DEMs
Sam Ekstrand *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 795-800 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The complication of the utilization of satellite data for forest decline assessment by topographic effects and variations in stand characteristics such as species composition and density is addressed. The possibility of using DEM's (Digital Elevation Models) and digitized stand data to reduce this problem was investigated for a forest region of Sweden. Variations in the hardwood component with 5 percent affected the accuracy of the Landsat TM (Thematic Mapper) based defoliation estimation, as did variations in the pine component with 12 to 15 percent and slope gradients as low as 4 to 5 deg. Based on the results a spruce defoliation model that uses slope/aspect data from elevation models and stand data from digitized forest maps to account for the mentioned error sources was developed. The resulting defoliation estimation was of adequate accuracy. The amount of work needed to digitize forest maps is considerable, but the method seems feasible on a provincial scale. ESA

SWEDISH FOREST INFORMATION ATLAS
M. Rosengren, L.-E. Gustafsson, and H. Oesterlund *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 801-804 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The production of a Swedish Forest Information Atlas (SFIA) derived from a digital terrain type classification database covering all of Sweden is reported. The database includes 900 map files each covering an area of 25 by 25 km with 50 m pixel size. Landsat TM (Thematic Mapper) and 12 SPOT scenes acquired 1988-90 were geocoded and classified into 13 terrain type classes. The statistical overall classification accuracy measured was 78 percent, while merging into 8 more generalized classes gave an overall accuracy of 84 percent. The SFIA was derived by extracting the classes of the Atlas as percentage images, describing the percentage of 50 m pixels within a 500 by 500 m area. The Forest Atlas comprises three forest classes extracted from these 'percentage images', open and closed coniferous forests, deciduous forest, as well as water, urban, and open areas. Additional cartographic elements will be superimposed on this classification. The atlas will be produced as printed maps and in digital format with a pixel size of 500 m. ESA

OBSERVATION OF FOREST DAMAGES IN THE HARZ MOUNTAINS BY MEANS OF SATELLITE REMOTE SENSING
H. Kenneweg, M. Schardt, and H. Sagischewski *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 805-810 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The use of satellite data for forest damage inventory in the Harz

mountains (Germany) is reported. From the results of signature analyses and of previous classifications the necessity to integrate auxiliary information by means of a geographic information system could be deduced. Digital terrain model forest planning data and soil maps are particularly useful for this purpose. In addition to the LANDSAT TM (Thematic Mapper) data, intensive field work and the interpretation of color infrared photos are needed as ground truth for: control areas representing damage classes, stand parameters and topographic influences on illumination; and control of accuracy of classification results. Data, methods, and resulting maps and tables are discussed. Change detection ('monitoring') is a matter of increasing importance, and this requires absolutely precise methods for geometrical and radiometrical correction of satellite data. ESA

TOWARD A SATELLITE BASED CROP INFORMATION SYSTEM IN HUNGARY
Gabor Csornai *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 813-815 Sponsored by Ministry of Agriculture, Hungary; State Board of Technical Development, Hungary; and Hungarian Academy of Sciences (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The validation of Landsat TM (Thematic Mapper) based crop area estimation methods on a complex 1.7 million hectares, three counties sample (19 percent) in Hungary is reported. In the stratification and sampling design procedures, historical production data were utilized. The area estimates for the major crops were very good, using satellite data. The study clearly indicated the potential of monotemporal Landsat TM data for crop area assessment, however, there are some problems left to be resolved. After the better understanding of the discrimination of the minor crop classes, the main problem will probably be stratification and sampling design. The extension of the methods to other areas and growing seasons is supposed to be relatively easy as well as the adaption of methods to multitemporal images. ESA

REMOTE SENSING OF LAND RESOURCE MANAGEMENT IN AGRICULTURE WITH REGARD TO ITS INFLUENCE ON THE ENVIRONMENT
K. Dockter and W. Kuehbauch *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 817-821 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The capability of remote sensing techniques (Landsat Thematic Mapper) for monitoring agricutural land management is described. Crop species identification and estimation of crop status, performed by remote sensing, enable analysts to assess the intensity level of land use. This information can be used to evaluate the influence of agricultural practices on the Earth's ecosystem. Remote sensing may help to control the extensification of today's high input farming. Satellite images reliably show crop rotation systems to comprise a high percentage of cereals. Nitrogen fertilization level can be monitored by remote sensing looking at the wavelength shift of the red edge inflection point. This is demonstrated for sugar beet and natural grassland. Both monoculture and intensive nitrogen fertilization lead to serious environmental problems and need to be monitored, as the protection of the natural resources becomes more and more important. ESA

ASSESSMENT AND FORECASTING OF CROP YIELD IN NIGER THROUGH NOAA NDVI DATA
F. Maselli, C. Conese, M. A. Gilabert (Valencia Univ., Burjassot, Spain.), and L. Petkov *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 823-827 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

NOAA NDVI (Normalized Different Vegetation Index) data were previously demonstrated to be correlated with annual rainfall and primary productivity in Sahelian areas, but these correlations are strongly affected by several environmental factors and were tested only with satellite data accumulated during whole rainy seasons. A methodology of NOAA AVHRR (Advanced Very High Resolution Radiometer) data processing is presented which utilizes NDVI computed only in the first part of some rainy reasons and statistically takes into account the geographical variability on land resources. Good results were obtained from an application of the methodology to Niger, especially for yield forecasting. ESA

INTEREST OF COMPLEMENTARY DATA OF COARSE AND HIGH SPATIAL RESOLUTION FOR AGRO-CLIMATIC CROP MONITORING
Ph. Puyou-Lascassies, M. Gay, and D. Peccoud *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 835-840 Sponsored by CNES (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The development of a deconvolution method for NOAA AVHRR (Advanced Very High Resolution Radiometer) data through knowledge of land use (SPOT data) is reported. The use of AVHRR temporal series to characterize the changes in land cover is still difficult in the complex agriculture landscapes of temperate countries. Complementary use of coarse and high spatial resolution data may make it possible to extract the part due to each of the agricultural themes present from the AVHRR signal. The method presented allows deconvolution of the AVHRR signal date to date on a local scale. The method was developed using SPOT data only, the coarse resolution signal being simulated by degrading the SPOT images. Because of the possibility that this simulation provided control of all the parameters, it enabled the reliability and sensitivity of the model to be studied. ESA

NORTH-CENTRAL MEXICO BLUE GRAMA RANGELAND BIOMASS ASSESSMENT AT THE END OF THE RAINY SEASON USING NOAA-AVHRR-LAC
R. Rene Garcia-Daguer *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 841-844 Sponsored by British Council, and CONACYT (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Normalized Difference Vegetation Index (NDVI) Local Area Coverage (LAC) data derived from the AVHRR (Advanced Very High Resolution

Radiometer) NOAA satellite for the 1990 end season growing period for the Mexican blue grama (Bouteloua gracilis) are compared with biomass estimates. A ground survey program was conducted in Aguascalientes, north central Mexico, involving both visual estimates and clipped plots (double sampling technique). Field measurements of biomass of herbaceous species were made for 22 sites in Nov. 1990. The sites were 1 sq km and were representative of the blue grama rangeland vegetation type. Relationship between NDVI and biomass was obtained through regression analysis. The correlation obtained was r squared = 0.79 when sites covered with trees were eliminated from the data set. ESA

CARTOGRAPHY AND STATISTICS OF CROPS UNDER IRRIGATION IN THE DONANA AREA OF ANDALUCIA THROUGH THE USE OF LANDSAT-TM IMAGERY AND ITS INCORPORATION INTO A GIS
A. FernandezPalacios and A. GonsalezF. *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 845-850 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The effect of an irrigation land use expansion in the surrounding area of the Donana National Park (Andalucia, Spain) since early 1970s is discussed. This is seriously disturbing the local aquifer reserves and, thereby, the conservation of the natural spaces. In order to better understand and anticipate management policies, a procedure involving sample methods, digital processing of Landsat data, and Geographic Information System (GIS) databases was developed to account for irrigated crops area estimation and spatial distribution. Because of the low cost and readily adaptable attitude, remote sensing approaches proved to be powerful tools versus traditional procedures when dealing with dynamic spatial phenomenon such as the one analyzed. ESA

REGISTRATION OF THE USE OF AGRICULTURAL FIELDS AND SOIL EROSION USING SATELLITE REMOTE SENSING
Dan Johan Weydahl and Rune Solberg (Norwegian Computing Center, Oslo.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 851-856 Sponsored by State-Pollution Control Authority, Norway (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The use of optical satellite for detecting tillage practices is discussed and the classification of fields using ERS-1 SAR (Synthetic Aperture Radar) images is described. Under the North Sea Agreement, Norway is obliged to reduce the discharge of nutrient salts from agricultural fields by 50 percent by 1995. Remote sensing from satellites can be used to monitor soil tillage in the areas concerned. An experiment was carried out which shows that it is possible to classify the different agricultural classes with a high degree of accuracy using either SPOT or LANDSAT Thematic Mapper images. However, cloud conditions in late Autumn make it interesting to investigate the use of satellite SAR images to detect tillage. The results of classifying SAR speckle reduced images, show that ploughed and stubble fields can be discriminated with a high degree of confidence when the soil moisture level is high. The best result is obtained using a field by field classification method. In an operational system, corrected SAR images should be used as a supplement to the optical images. ESA

BIODIVERSITY INDICATION BY EARTH OBSERVATION DATA
Thomas Allner, Robert Backhaus, Steve Gaito (Forschungszentrum Juelich G.m.b.H., Germany.), and Jacqueline McGlade (Forschungszentrum Juelich G.m.b.H., Germany.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 863-867 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An approach to biodiversity monitoring is presented. With the thematic approach, the range of Earth observation data suitable for application is limited by the number of objects (geophysical formations, vegetation classes, landscape elements, types of habitats, etc.) which can be positively identified with a reasonable degree of certainty. The thematic approach, however, does not take into account another type of information which may be derived from existing and future Earth observation data sets merely by virtue of their topological structure. From recent results and theoretical considerations, it is assumed that suitable indicators of habitat diversity can be derived from the structural/topological information content of multispectral satellite data covering specific ecosystems. To further evaluate and demonstrate this information potential of satellite data, a diversity index is proposed, which was tentatively applied to a LANDSAT Thematic Mapper scene of the Bavarian Forest National Park. First results are presented, and implications of these results with relation to the feasibility of biodiversity indication based on the information content of satellite image data are discussed. ESA

MEASURING THE INTENSITY OF NITROGEN FERTILIZATION OF GRASSLAND BY MEANS OF REMOTE SENSING
C. Bueker, J. G. P. W. Clevers, and W. Kuehbauch (Bonn Univ., Germany.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 869-872 (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An investigation of the red edge shift in imaging spectrometer data of a grassland site in Somerset (England) showed that nitrogen treatment effects could be ascertained with larger power by means of the red edge shift than by means of a vegetation index. Moreover, the position of the red edge index was best correlated with canopy parameters like biomass and chlorophyll concentration. The research showed that the position of the red edge reveals the level of nitrogen fertilization with good precision and therefore offers valuable additional information for agricultural research. Four narrow spectral bands at 670, 700, 740, and 780 nm can be used for determining the position of the red infrared slope. ESA

COMBINING SPECTRAL INFORMATION WITH CROP ROTATION KNOWLEDGE FOR CROP CLASSIFICATIONS
Changyuan Ji *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 881-884 Sponsored by EEC (For primary document see N93-24775 09-43)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

First and second order state transition matrices were derived from crop rotation system knowledge, which represent the temporal relationship of crop transitions in a two and three year lap respectively. Classifications were implemented using SPOT High Resolution Visible data together with the transition matrices. Knowledge of crop temporal relationships represented by state transition matrices is concluded to improve crop classification when combined with spectral data of satellite images. The increase depends on the spectral separability of the image data. Depending on the data set used, the overall accuracy of eight agricultural classes is increased by 5 to 15 percent over the standard maximum likelihood classifications using the first order matrices. The 2nd order transition matrices, together with the 1st order matrices, even further improve crop classifications. It is recommended that the method be applied when ground data of cropping information are available. ESA

A method to correct atmospheric effects on Landsat TM (Thematic Mapper) data over mountainous terrain in the solar spectrum, developed primarily for forestry applications, and which can also be adapted to other sensors and applications is described. The algorithm automatically identifies patches of dark, dense vegetation as controllable dark surfaces for the estimation of the aerosol optical thickness. Thereby, a network of radiometric control points is laid over the scene which supply horizontal as well as relief induced vertical changes in atmospheric conditions. Atmospheric parameters calculated with the LOWTRAN program over these pixels are smoothed and interpolated by cubic spline regression. With these values, atmospherically corrected ground reflectances are calculated pixelwise by iteration of a correction model. Improvements in visual interpretation, in the standardization of photoproducts, and in the use of calibrated data with multitemporal applications are discussed. ESA

A concept for updating and revision of forest maps and associated tabular data using satellite remote sensing and GIS (Geographic Information System) techniques is presented. The method is based on integrated use of visual interpretation, image segmentation, ocular field inventory, and statistical estimation techniques. The methodology was implemented on a PC based GIS/remote sensing workstation for forestry. The system was used by a forest company for update and revision of a 5083 hectare management unit. The experiences gained indicated a potential for substantial cost savings and several other advantages compared to the conventional methods used in practice. The experiment also showed that the technique can be customized to be used at the local level in the forestry organization. ESA

The reflection of Scots pine (Pinus sylvestris L.) needles was examined in Autumn in traffic environment in order to study the usability of reflection information for forest damage detection. The atmospheric concentrations of nitrogen oxides, ozone, and sulphur dioxide were measured and a mapping of epiphytic lichens, indicating the biological effects of the measured atmospheric impurities, was performed. The trees, forming a line perpendicular to a highway and thus suffering from different amounts of environmental stress factors at different distances, were photographed in the field on black and white infrared film. Needle samples were also collected for macro and microscopical IR photography, scanning electron and light microscopy, and chemical analysis. The reflection of single needles was then studied more accurately by spectrometer measurements both beside the highway and in background area. ESA

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Spectral measurements were made from a helicopter at four different altitudes for a range of types of deciduous woodland. For seminatural woodlands, while visible reflectance remained constant, near infrared reflectance decreased as the size of area being sensed by the spectroradiometer increased. This raises important implications for the remote sensing of complex vegetation canopies. In remotely sensed imagery from different sensors, and from the same sensor at different altitudes, the area covered by a pixel varies. Therefore, as a result of the scale dependence identified in this experiment, the remotely sensed signal recorded from the same area of deciduous woodland will be different in the images from these different sources. This may impose limitations on the use of such data both in terms of the information from broadband analysis (for example estimating leaf area index) and from specific spectral features such as the red edge (for example monitoring stress). INFLUENCE DUE TO ANTENNA PATTERN CHANGE IN BRIGHTNESS TEMPERATURE ESTIMATION FOR A SPACE-BASED MICROWAVE RADIOMETER

Kohei Arai, Kenbu Teramoto, and Toshio Imatani (Mitsubishi Electric Corp., Kanagawa, Japan.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 913-916 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An assessment of the influence due to antenna pattern changes in brightness temperature estimation taking into account antenna pattern correction for a space based microwave radiometer is reported. Boresight direction and asymmetry of the antenna pattern, in general, are changed in space due to thermal stress, mechanical stress or vibrations, and so forth. In order to estimate brightness temperature of targets, antenna pattern correction is necessary. In such a case, although an accurate real antenna pattern is needed, it is not possible in space. Therefore, some assessments of the influence due to antenna pattern changes in brightness temperature is required. Simulated antenna pattern was generated using actual antenna pattern taking into account a realistic distortion due to the aforementioned defects. The results show the influence for the case with antenna pattern correction is greater than that for the case without antenna pattern correction. The results suggest a required accuracy in antenna pattern measurement and allowable noise. ESA

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The creation of a program for adaptive control of data acquisition and processing of video data and multichannel images is discussed. Systems for remote sensing of the Earth and environment monitoring generate large volumes of information. Large space projects need special expensive technical means for data and image acquisition. A way to reconcile the controversy between the ever increasing volume of data and the time for its processing is believed to be the use of a specific transputer computing architecture in airborne and space measurement systems. The transputer concept makes use most efficiently of the natural parallelisms in the data streams, their mutual correlation, and information redundancy. ESA

EUROSTARS: A SYSTEM FOR THEMATIC ANALYSIS OF REMOTE SENSED DATA

S. Pfleger, A. Siebert, and M. Cantone (Bonifica S.p.A., Rome, Italy.) *In* ESA, Environment Observation and Climate Modelling Through International Space Projects. Volume 2: Remote Sensing for Environmental Monitoring and Resource Management 1992 p 929-932 (For primary document see N93-24775 09-43)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The central point of the EUROSTARS (European System for Thematic Analysis of Remote Sensed Data) project, started in 1991, is the development of a new methodology of geographical analysis based on remote sensed images (satellite data) using neural networks and knowledge based terrain modeling. The processes of segmenting and classifying the information content of an image are guided by a neural network, which is able to correctly interpret the results related to the attributes of the extracted features like context, form, geometry, texture, and radiance. Classification will assign a semantic meaning to the extracted features, based on a specified human classification criterion. Self learning experiments based on examples will support an optimal calibration of the neural network; the accuracy of the obtained results will be evaluated by comparing them with the results obtained by traditional image processing and interpretation procedures. The attempted measurement of the bioelectric potential of silk trees in Naples zoo is reported. Many small earthquakes occur in the south of Italy, and on 26 May 1991 a moderate earthquake (M = 4.6) occurred in the Lucania area. The anomalous bioelectric potential changes in the silk trees on 25 May (about 24 hours before the earthquake) are presented. The development of interdisciplinary studies regarding physics, geoelectromagnetics, geochemistry, electroengineering, plant physiology, and animal physiology is suggested as an eventual way to predict earthquakes. All the NASA VEGetation Workbench (VEG) goals except the Learning System provide the scientist with several different techniques. When VEG is run, rules assist the scientist in selecting the best of the available techniques to apply to the sample of cover type data being studied. The techniques are stored in the VEG knowledge base. The design and implementation of an interface that allows the scientist to add new techniques to VEG without assistance from the developer were completed. A new interface that enables the scientist to add techniques to VEG without assistance from the developer was designed and implemented. This interface does not require the scientist to have a thorough knowledge of Knowledge Engineering Environment (KEE) by Intellicorp or a detailed knowledge of the structure of VEG. The interface prompts the scientist to enter the required information about the new technique. It prompts the scientist to enter the required Common Lisp functions for executing the technique and the left hand side of the rule that causes the technique to be selected. A template for each function and rule and detailed instructions about the arguments of the functions, the values they should return, and the format of the rule are displayed. Checks are made to ensure that the required data were entered, the functions compiled correctly, and the rule parsed correctly before the new technique is stored. The additional techniques are stored separately from the VEG knowledge base. When the VEG knowledge base is loaded, the additional techniques are not normally loaded. The interface allows the scientist the option of adding all the previously defined new techniques before running VEG. When the techniques are added, the required units to store the additional techniques are created automatically in the correct places in the VEG knowledge base. The methods file containing the functions required by the additional techniques is loaded. New rule units are created to store the new rules. The interface that allow the scientist to select which techniques to use is updated automatically to include the new techniques. Task H was completed. The interface that allows the scientist to add techniques to VEG was implemented and comprehensively tested. The Common Lisp code for the Add Techniques system is listed in Appendix A. PASSIVE MICROWAVE REMOTE SENSING OF SNOW-COVERED FLOATING ICE DURING SPRING CONDITIONS IN THE ARCTIC AND ANTARCTIC Ph.D. Thesis
Caren Garrity 1991 350 p
(ISBN-0-315-70444-6) Avail: Univ. Microfilms Order No. DANN70444

It is possible to classify first year from multi-year ice during the onset of melt period using a dual-polarized 37 GHz radiometer. The classification is based on the emission from the snow cover instead of from the sea ice when the snow is not dry. There can be large diurnal fluctuations in the brightness temperature, as large as 80K, but there is a particular time of day when there will be a separation in the brightness temperature of first year compared to multi-year ice. This separation is due to the stage of metamorphism of the snow, which is a function of the temperature gradient in the snow and will be different for each ice type. A snow cover on first year ice is typically thinner than for multi-year ice. This thinner snow cover is influenced by environmental conditions at a faster rate than for a thicker snow cover due to the insulating property of snow. Generally, the afternoon period is a good time for ice classification using a passive microwave sensor. However, during the initial stages of the onset of melt, the morning hours would be a better time for a satellite overpass. This indicates that for ice classification, an overpass of a radiometer bearing satellite, such as the Special Sensor Microwave Imager (SSM/I), would be best in the morning during the mid-spring, and afternoon during the later spring for the high Arctic. A curve showing the stages of snow metamorphism from snow covered sea ice has been established using 37 GHz brightness temperatures. Therefore, the stage of metamorphism in a snow cover can be obtained from the curve. The onset of melt is well defined from the brightness temperature. If the brightness temperature is greater than that for sea ice, the snow cover contains from 1 percent to 6 percent free-water by volume. If the brightness temperature is lower than that measured for sea ice, and the signal is depolarized (vertical and horizontal brightness temperatures are similar), then the snow is dry. The amount of volume scattering in a dry snow cover will decrease the brightness temperature with increasing snow depth. Once snow depth and density are obtained, the amount of water a snow cover contains, known as water equivalent, can be determined. If the brightness temperature is low and polarized, there could be slush at the snow-ice interface. Mapping of slush on sea ice would be a useful parameter to shipping since slush will reduce the speed of a ship. Dissert. Abstr.

N93-25430 Purdue Univ., West Lafayette, IN.
INTEGRATING SATELLITE IMAGERY AND DIGITAL ELEVATION DATA FOR GEOBOTANICAL MAPPING IN QUETICO PROVINCIAL PARK, ONTARIO, CANADA Ph.D. Thesis
Timothy Andrew Warner 1992 93 p
Avail: Univ. Microfilms Order No. DA9301405

This geobotanical remote sensing study of a granite-greenstone terrain in eastern Quetico Provincial Park, north-western Ontario, Canada, is based on a topographic analysis of digital elevation data. The greenstone units consist of metamorphosed mafic and occasional ultramafic lithologies, surrounded by granites and granodiorites. Glacial till is thin and capped by loess in places. The soils are mainly Inceptisols, Histosols and Boralfs. The vegetation is dominantly boreal in nature. The digital elevation data analysis identified four microclimate and drainage classes. Landsat Thematic Mapper (TM) data were transformed into the nPDF Deciduous Forest Index and then density sliced in six informational classes of various deciduous and coniferous cover. The distribution of forest classes on each of the two lithologies shows that stands growing on mafic lithologies are enriched in deciduous species, compared to those growing on granites. Of the cover classes found on mafics, the highest coniferous component was on north facing slopes, and the highest deciduous component on south facing slopes. By contrast, granites showed no appreciable variation between site classes. These associations were then applied in an integrated, rule-based classification that utilizes average community vegetation, topographic landscape units and aeromagnetic anomalies to separate greenstone belts from surrounding granitic areas. The procedure, called Topoveg, is not overtly hampered by scattered clouds in the area, since areas that are obscured or have no forests on adjacent south facing slopes are assumed to be similar to their surrounding areas. Topoveg achieved an 85.0 percent accuracy in a classification of the 10 by 13 kilometer primary test site. A

standard maximum likelihood classification had an accuracy of only 71.3 percent, and produces output that has a distinctive noisy texture, compared to the large, homogenous classes of Topoveg. In a neighboring test site to the north, Topoveg accuracy was similarly high (86.3 percent). The southern test site, however, had an increased percentage of deciduous species on south facing granitic sites, and consequently a lower accuracy (78.6 percent). Thus these particular classification rules may be used with confidence in areas to the north, east and west. New rules should be developed for classification of areas to the south. Dissert. Abstr.

N93-25434 California Univ., Santa Barbara.
MULTI-TEMPORAL SATELLITE IMAGE ANALYSIS FOR CROP INVENTORIES IN THE PO RIVER VALLEY (ITALY) Ph.D. Thesis
Daniele Ehrlich 1992 180 p
Avail: Univ. Microfilms Order No. DA9303185

This dissertation describes satellite data image processing for crop area estimation in Veneto region (Italy). Several quantitative image analysis exercises were carried out to investigate the information content of Landsat Thematic Mapper imagery with reference to the landscape of the Veneto region. These exercises include multi-temporal image normalization, multi-temporal image classification of selected study sites, 'greenness' temporal profile modeling and development of an advanced agricultural information system for the integration of different data types describing the landscape for an optimal crop area estimation. Multi-temporal image normalization was performed using the procedure which relies only on spectral information contained in satellite imagery. The procedure is extendible to different images and to images acquired in different growing season. The procedure worked well especially for correcting systematic radiometric variation such as offsets in radiometric calibration coefficients, sun angle differences and uniform variation in atmosphere turbidity. Multi-temporal image classification at selected study sites was conducted to identify pattern of crop growth as detected from spectral imagery. Three study sites, each containing four annual crops under study were classified using several pattern recognition techniques. The image analysis revealed phenology related spectral crop pattern which were used to separate the crop under study. Crop classification accuracies as computed in the study sites yielded accuracies which range between 71 percent to 82 percent according to the crop and the area under investigation. Greenness temporal profile modeling, an image processing technique which exploits graphical shape rather than statistical characteristic of the image was also attempted for an improved crop type classification. Temporal profile analysis provided additional information on spectral properties of crops through time. Classification accuracy results obtained with temporal profile analysis resulted being comparable to pattern recognition techniques. Finally, knowledge on the information content of Landsat Thematic Mapper images combined with knowledge on the processes occurring on the landscape were combined in an image processing procedure which uses both image processing algorithms and geographic information system operations. Image analysis has been conducted within the framework of an advanced agricultural information system (AAIS). The AAIS is a raster based geographic information system which integrates several data types including satellite imagery, analog map data and ancillary information in the form of knowledge about the processes occurring in the landscape. The system is open to new input and can continuously be updated upon the arrival of new information. As such AAIS is a model which quantitatively describes some important components of the agricultural system and can be used to predict physical as well as social processes in the landscape. Dissert. Abstr.

N93-25441 North Carolina State Univ., Raleigh.
AERIAL PHOTOGRAPHIC SAMPLING FOR STATEWIDE RESOURCE INVENTORY Ph.D. Thesis
Glenn Paul Catts 1992 295 p
Avail: Univ. Microfilms Order No. DA9305422

The land use and forest resource conditions of the state of North Carolina were photointerpreted from 1:12,000 scale, color infrared aerial photography. Nearly 400 circular plots, of 1000 acres in area, were type mapped by two photointerpreters according to classification definitions adopted from those of the Southeastern Forest Inventory and Analysis (SE FIA) unit of the U.S. Forest Service. Photo plots were arranged in a statewide systematic layout. Four classification levels were used. The initial 1000 acre plot size was further subdivided into six smaller concentric plot sizes. Acreage photointerpreted was converted into a percentage estimate for each plot by forming a ratio of the number of acres type mapped in the class over the total number of acres in the plot. Regional and statewide percentage estimates for all classes in all classification schemes and for all plot sizes were produced separately. Fieldwork was conducted at nearly 300 locations imaged by the aerial photography. Results of coincident fieldwork and photointerpretation were cross-tabulated into a series of error matrices used to adjust the initial percentage estimates for classification bias. The precision of the percentage estimates was calculated using a Monte Carlo simulation technique known as bootstrapping. Accuracy of the percentage estimates was assessed by comparison with temporally coincident SE FIA 5th Survey results (1982-1984). The influence on precision of the numbers and size of the sample plots photointerpreted, and the number of coincident plots used to build the error matrix was investigated. An optimization model was formulated with the objective of finding a minimum total cost for a multiresource survey design meeting predetermined, class specific precision requirements. Photointerpretation was found to be accurate and consistent among the most experienced individuals. Adjusted class percentage estimates were closer to SE FIA estimates than were unadjusted for many classes. Bootstrapped confidence intervals contained SE FIA field survey estimates. Solutions to the minimization model indicated that photointerpretation of plots in sizes above 800 acres were most cost effective in an example examined. Optimization modeling could assist resource managers in choosing most efficient multiresource survey designs. Dissert. Abstr.

EARTH OBSERVING SYSTEM. OUTPUT DATA PRODUCTS AND INPUT REQUIREMENTS, VERSION 2.0. VOLUME 1: INSTRUMENT DATA PRODUCT CHARACTERISTICS
Yun-Chi Lu, Hyo Duck Chang, Brian Krupp, Ravindra Kumar, and Anand Swaroop Aug. 1992 189 p
(NASA-TM-108770; NAS 1.15:108770) Avail: CASI HC A09/MF A02

Information on Earth Observing System (EOS) output data products and input data requirements that has been compiled by the Science Processing Support Office (SPSO) at GSFC is presented. Since Version 1.0 of the SPSO Report was released in August 1991, there have been significant changes in the EOS program. In anticipation of a likely budget cut for the EOS Project, NASA HQ restructured the EOS program. An initial program consisting of two large platforms was replaced by plans for multiple, smaller platforms, and some EOS instruments were either deselected or descoped. Updated payload information reflecting the restructured EOS program superseding the August 1991 version of the SPSO report is included. This report has been expanded to cover information on non-EOS data products, and consists of three volumes (Volumes 1, 2, and 3). Volume 1 provides information on instrument outputs and input requirements. Volume 2 is devoted to Interdisciplinary Science (IDS) outputs and input requirements, including the 'best' and 'alternative' match analysis. Volume 3 provides information about retrieval algorithms, non-EOS input requirements of instrument teams and IDS investigators, and availability of non-EOS data products at seven primary Distributed Active Archive Centers (DAAC's). Author (revised)

N93-25461*# National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.
EARTH OBSERVING SYSTEM. OUTPUT DATA PRODUCTS AND INPUT REQUIREMENTS, VERSION 2.0. VOLUME 2: ANALYSIS OF IDS INPUT REQUIREMENTS
Yun-Chi Lu, Hyo Duck Chang, Brian Krupp, Ravindra Kumar, and Anand Swaroop Aug. 1992 197 p
(NASA-TM-108771; NAS 1.15:108771) Avail: CASI HC A09/MF A03

On 18 Jan. 1991, NASA confirmed 29 Inter-Disciplinary Science (IDS) teams, each involving a group of investigators, to conduct interdisciplinary research using data products from Earth Observing System (EOS) instruments. These studies are multi-disciplinary and require output data products from multiple EOS instruments, including both FI and PI instruments. The purpose of this volume is to provide information on output products expected from IDS investigators, required input data, and retrieval algorithms. Also included in this volume is the revised analysis of the 'best' and 'alternative' match data products for IDS input requirements. The original analysis presented in the August 1991 release of the SPSO Report was revised to incorporate the restructuring of the EOS platform. As a result of

the reduced EOS payload, some of EOS instruments were deselected and their data products would not be available for IDS research. Information on these data products is also presented. Author (revised)

EARTH OBSERVING SYSTEM. OUTPUT DATA PRODUCTS AND INPUT REQUIREMENTS, VERSION 2.0. VOLUME 3: ALGORITHM SUMMARY TABLES AND NON-EOS DATA PRODUCTS
Yun-Chi Lu, Hyo Duck Chang, Brian Krupp, Ravindar Kumar, and Anand Swaroop Aug. 1992 227 p
(NASA-TM-108769; NAS 1.15:108769) Avail: CASI HC A11/MF A03

Volume 3 assists Earth Observing System (EOS) investigators in locating required non-EOS data products by identifying their non-EOS input requirements and providing the information on data sets available at various Distributed Active Archive Centers (DAAC's), including those from Pathfinder Activities and Earth Probes. Volume 3 is intended to complement, not to duplicate, the the EOSDIS Science Data Plan (SDP) by providing detailed data set information which was not presented in the SDP. Section 9 of this volume discusses the algorithm summary tables containing information on retrieval algorithms, expected outputs and required input data. Section 10 describes the non-EOS input requirements of instrument teams and IDS investigators. Also described are the current and future data holdings of the original seven DAACS and data products planned from the future missions and projects including Earth Probes and Pathfinder Activities. Section 11 describes source of information used in compiling data set information presented in this volume. A list of data set attributes used to describe various data sets is presented in section 12 along with their descriptions. Finally, Section 13 presents the SPSO's future plan to improve this report . This paper describes a preliminary sensory system for real-time sensor-based navigation in a three-dimensional, dynamic environment. Data from a laser range camera are processed on an iWarp parallel computer to create a 3D occupancy map. This map is rendered using raytracing. The construction and rendering consume less than 800 milliseconds. DOE

We have developed an integrated framework for the efficient synthesis of realistic images of three dimensional terrain with man-made objects and natural clutter. We have shown how many phenomenological aspects of the placement of road networks, tree clusters, populated areas, buildings, etc., can be captured in a computationally-efficient pseudorandom image-generation framework. We generate the underlying terrain with a fast Fourier based procedure. This procedure is seeded with a pseudorandom sequence, so a small number of parameters can characterize a distinctive class of terrain. Within each class, arbitrarily many scenes can be synthesized. We have used procedural definitions for objects; targets or clutter are represented by different models depending on range. For example, at a great distance trees may look like simple cones. But, as the viewpoint nears a tree, finer details will become visible. Procedural definitions also eliminate the need to explicitly store boundary representations for every object placed in the scene. A single procedural definition for an object, such as a tree, can be used at render time by a Z-buffer algorithm to create as many instances as are necessary, with each instance being unique since it uses a unique pseudorandom seed. The radar has been upgraded through improvements to the receiver and addition of an inexpensive PC-based Digital Signal Processing system to allow real-time processing and display of radar parameters. A Sun Microsystems SPARCstation was added to the system for processed data archive as well as post analysis. The radar system was shipped to Kennedy Space Center for electrification studies during the summer of 1991. DTIC

DETECTING THE SCALE AND RESOLUTION EFFECTS IN REMOTE SENSING AND GIS Ph.D. Thesis
Changyong Cao 1992 222 p
Avail: Univ. Microfilms Order No. DA9302893

The relationship between resolution and fractal dimensions of remotely sensed images is examined. Based on the results of testing for the reliability of the algorithms on hypothetical surfaces, the isarithm algorithm is selected for determining the fractal dimensions of remotely sensed images. This algorithm is then applied to simulated fractal Brownian motion images and four calibrated airborne multispectral remotely sensed image data sets with different true and artificial resolutions for Puerto Rico. The results from applying the fractal method to images at different levels of resolution suggest that the higher the resolution of an image, the higher the fractal dimension of the image and the more complex the image surface. This relationship between resolution and fractal dimension is further verified by results from analysis employing the local variance method for the same data sets; where it is found that the higher the resolution, the higher the local variance or the more complex the image surface. The images with artificial resolutions were found to be unrealistic in simulating images with different resolutions because the aggregate method used in generating these images does not exactly simulate the sensor's response to resolution changes. The aggregate method was widely used in image resampling and cautious use of this algorithm is suggested in future studies. The findings show that the fractal method is a useful tool in detecting the scale and resolution effects of remotely sensed images and in evaluating the trade-offs between data volume and data accuracy. More studies employing fractals and other spatial statistics to images with different artificial resolutions generated using better aggregation algorithms are needed in the future in order to further detect the scale and resolution effects in remote sensing and Geographic Information Systems (GIS). RELATIONS BETWEEN BLUE WHITING BIOMASS AND SATELLITE DERIVED PHYTOPLANKTON AND TEMPERATURE IN THE NORWEGIAN SEA Final Report
R. A. Arnone, R. A. Oriol, and R. Nero Sep. 1992 28 p
(AD-A261205; NRL/MR/7240-92-7009; NOARL-TN-153) Avail: CASI HC A03/MF A01

The abundance of blue whiting in the Norwegian Sea is correlated with surface phytoplankton concentration and sea surface temperature (SST) measured from satellite. The distribution and abundance of fish has significant impact on active acoustic volume reverberation. Acoustic fish abundance ship surveys conducted in the Norwegian Sea in August from 1984 to 1986 were analyzed for relationships with the monthly coincident average surface phytoplankton and SST. Little correlation was observed between blue whiting and phytoplankton or SST separately suggesting that fish distributions are better coupled with a multiparameter approach. The spatial and temporal averaging of high resolution satellite imagery may inhibit correlations. Features such as ocean fronts are prime contributors to fish abundance distribution. Average ocean properties (such as phytoplankton concentration or SST) can mask the local ocean events that are partially responsible for fish distribution. DTIC

US ARMY EVALUATION OF THE ELECTRONIC MAP DATA (EMD) PROTOTYPE Technical Report, Nov. 1990 - Dec. 1991
John P. Bradley Dec. 1992 135 p
(AD-A261693; TEC-0026) Avail: CASI HC A07/MF A02

This report provides a consolidated U.S. Army evaluation of the Electronic Map Data (EMD) prototype. This prototype was developed by the Digital Concepts and Analysis Center (DCAC) of the U.S. Army Topographic Engineering Center (USATEC). The intent of this prototype was to refine Army map background requirements by providing a real example of an alternative product. Participants in the evaluation included program managers and support contractors representing the Army components, government agencies, and private industry. Overall, evaluator comments indicated that EMD, as defined by the prototype, cannot be definitively recommended as the Army's standard map background product. Although the color separate approach does provide desirable capabilities not afforded by a composite image map, these advantages are outweighed by inherent limitations associated with decluttering by color. From user feedback indications, the original documented map background requirement submitted to DMA, which was for a product that contains declutterable feature data, requires minimal storage, and provides normalized color across map sheets, remains unchanged. ATMOS: LONG TERM ATMOSPHERIC MEASUREMENTS FOR MISSION TO PLANET EARTH
1992 15 p Original contains color illustrations
(NASA-TM-108720; NAS 1.15:108720) Avail: CASI HC A03/MF A01; 10 functional color pages

A long-term, space-based measurement program, together with continued balloon and aircraft-borne investigations, is essential to monitor the predicted effects in the atmosphere, to determine to what extent the concentration measurements agree with current models of stratospheric chemistry, and to determine the condition of the ozone layer. The Atmospheric Trace Molecule Spectroscopy (ATMOS) Experiment is currently making comprehensive, global measurements of Earth's atmosphere as part of the Atmospheric Laboratory for Applications and Science (ATLAS) program on the Space Shuttle. Part of NASA's Mission to Planet Earth, ATLAS is a continuing series of missions to study Earth and the Sun and provide a more fundamental understanding of the solar influences on Earth's atmosphere. The ATMOS program, instruments, and science results are presented. Derived from text

EXPERIMENTS IN MULTIPLE-BASELINE STEREO Research Report
Tomoharu Nakahara and Takeo Kanade Aug. 1992 37 p
(Contract F33615-90-C-1465)
(AD-A261415; CMU-CS-92-103) Avail: CASI HC A03/MF A01

This paper presents the results of our experiments with a unique multiple-baseline stereo technique. This algorithm for producing precise, unambiguous depth maps from a set of multiple stereo pairs was developed by Okutomi and Kanade. Early versions of the algorithm were shown to perform well under controlled conditions in the Calibrated Imaging Laboratory (CIL). In this paper, the algorithm is further applied to complex outdoor scenes with variable lighting conditions and large depth ranges. While Okutomi and Kanade used stereo pairs acquired by moving a camera horizontally, we also investigated the use of stereo pairs taken by moving a camera in both horizontal and vertical directions. The use of stereo images with two orthogonal baseline orientations removes ambiguity and increases precision without the problems associated with the orientation of the features in a scene. We also show that the shapes of the sum of squared-difference (SSD) curve indicates the reliability of the match, and suggest a method to classify matches into various types and to improve estimates when a false match occurs. Finally, results are presented to show the effectiveness of this algorithm and the classification method. DTIC

IMPLEMENTATION OF CUSTOM COLORS IN THE DECWINDOWS ENVIRONMENT
Stephanie A. Myrick and Perry B. Wischow Dec. 1992 12 p Presented at the DECUS Fall Symposium held in Las Vegas, NV, 5-11 Dec. 1992
(AD-A261456; NRLD-PR-92-085-351) Avail: CASI HC A03/MF A01

This paper describes the implementation of user-defined, or custom, colors in the DECwindows environment. Custom colors can be used to augment the standard color set that is associated with the hardware colormap. The custom color set that is included in this paper consists of 240 distinct colors, each of which is comprised of red, green, and blue intensities. Intensity levels range from zero (no intensity) to 255 (maximum intensity). The DECwindow and Xwindow statements, which are required to implement the custom color set, are identified and described. Some of the tasks performed by these statements include creating and installing a colormap and accessing individual colors. Using a VAX C programming language platform, examples of proper invocation and syntax of these statements are provided. Some familiarization with C, DECwindows and Xwindows is assumed. DTIC

AN EVALUATION OF THERMAL ENERGY STORAGE OPTIONS FOR PRECOOLING GAS TURBINE INLET AIR
Z. I. Antoniak, D. R. Brown, and M. K. Drost Dec. 1992 32 p
(Contract DE-AC06-76RL-01830)
(DE93-005980; PNL-8427) Avail: CASI HC A03/MF A01

Several approaches have been used to reduce the temperature of gas turbine inlet air. One of the most successful uses off-peak electric power to drive vapor-compression-cycle ice makers. The ice is stored until the next time high ambient temperature is encountered, when the ice is used in a heat exchanger to cool the gas turbine inlet air. An alternative concept would use seasonal thermal energy storage to store winter chill for inlet air cooling. The objective of this study was to compare the performance and economics of seasonal thermal energy storage in aquifers with diurnal ice thermal energy storage for gas turbine inlet air cooling. The investigation consisted of developing computer codes to model the performance of a gas turbine, energy storage system, heat exchangers, and ancillary equipment. The performance models were combined with cost models to calculate unit capital costs and levelized energy costs for each concept. The levelized energy cost was calculated for three technologies in two locations (Minneapolis, Minnesota and Birmingham, Alabama). Precooling gas turbine inlet air with cold water supplied by an aquifer thermal energy storage system provided lower cost electricity than simply increasing the size of the turbine for meteorological and geological conditions existing in the Minneapolis vicinity. A 15 to 20 percent cost reduction resulted for both 0.05 and 0.2 annual operating factors. In contrast, ice storage precooling was found to be between 5 and 20 percent more expensive than larger gas turbines for the Minneapolis location. In Birmingham, aquifer thermal energy storage precooling was preferred at the higher capacity factor and ice storage precooling was the best option at the lower capacity factor. In both cases, the levelized cost was reduced by approximately 5 percent when compared to larger gas turbines. DOE

COMPUTATIONAL AND EXPERIMENTAL STUDIES ON LARGE SCALE SOLAR HEATING Ph.D. Thesis
S. Peltola 1992 60 p
(DE93-769942; TKK-NEMO-19) Avail: CASI HC A04/MF A01

The experimental part of the work deals mainly with the experiences gained from the Kerava Solar Village (KSV) but some additional remarks are presented from international studies. The measured thermal performance of the KSV heating system indicates considerably poorer performance than original design values. Reasons for this are studied by means of computational analyses. Fundamental problems with KSV systems was too small storage size with respect both to installed collector area and connected load. From an operational point of view, the frequent heat pump failures were the most severe problem. Computational tools for large solar heating system design and analyses are presented. Numerical models developed in this work, the KERCONT and SUPERSOL, are validated with measured performance from the KSV indicating reasonably good accuracy. The tools have been applied for detecting KSV heating system problems and for finding solutions for them as well as for re-design of the system. More general analyses are presented on the applicability of the KSV system principle in other load sizes and locations. A new approach for preliminary studies on Central Solar Heating Plants with Seasonal Storage (CSHPSS) is described. The analytical model, SOLCHIPS, is shown to be a very effective tool for pre-design studies. The validity of SOLCHIPS approach is studied by comparing the results against results from validated numerical model, MINSUN. In the last part of the work, preliminary results from numerical simulations of summer time district solar heating with short term storage are presented. According to the analyses, these systems should provide heat at or below the cost achievable with seasonal storage systems. DOE

ADVANCED ENERGY SYSTEMS AND TECHNOLOGIES - NATIONAL R AND D PROGRAMME
P. D. Lund Aug. 1992 64 p
(DE93-769943; TKK-NEMO-21) Avail: CASI HC A04/MF A01

The energy R and D in Finland is accomplished through the energy research programs of the Ministry of Trade and Industry. Today there are some 12 R and D programs in operation covering the various aspects of the energy sector. The NEMO-program deals with advanced new energy technologies and systems. The NEMO-program was launched in 1988 and it ends at the end of 1992. Helsinki University of Technology has been responsible for the coordination and most of the universities, research centers, and companies on new advanced energy technologies have been involved in the realization of NEMO. The objectives of the program have been to assess the potential of new technologies in the Finnish energy supply system, encourage and support businesses, and to create necessary research tradition in Finland. At the beginning in year 1988, several new technologies were included, but as the knowledge has increased, focusing on the most promising fields has taken place. Wind and solar energy show the best promises in respect to business activities and possibilities for utilization in Finland. Energy storage some other advanced technologies such as fuel cells and hydrogen technologies represented in the NEMO-program have an important role, but the commercial applications lie more distant in the future. The NEMO-program has reached its objectives. The international evaluation in fall 1990 gave very positive feedback and the scientific quality of the work was found good. At the same time, the contents was still focused more on commercial applications to support national industries in the field. The descriptions of the ongoing NEMO research projects are included in this report. DOE

NEW CONCEPTS FOR HIGH EFFICIENCY ENERGY CONVERSION: THE AVALANCHE HETEROSTRUCTURE AND SUPERLATTICE SOLAR CELLS
C. J. Summers, A. Rohatgi, A. Torabi, and H. M. Harris Jan. 1993 118 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE92-010592; NREL/TP-410-4960) Avail: CASI HC A06/MF A02

This report describes an investigation into the theory and technology of a novel heterojunction or superlattice, single-junction solar cell, which injects electrons across the heterointerface to produce highly efficient impact ionization of carriers in the lowband-gap side of the junction, thereby conserving their total energy. Also, the superlattice structure has the advantage of relaxing the need for perfect lattice matching at the p-n interface and will inhibit the cross diffusion of dopant atoms that typically occurs in heavy doping. This structure avoids the use of tunnel junctions that make it very difficult to achieve the predicted efficiencies in cascade cells, thus making it possible to obtain energy efficiencies that are competitive with those predicted for cascade solar cells with reduced complexity and cost. This cell structure could also be incorporated into other solar cell structures designed for wider spectral coverage. DOE

AN INVERTED AlGaAs/GaAs PATTERNED-Ge TUNNEL JUNCTION CASCADE CONCENTRATOR SOLAR CELL
R. Venkatasubramanian Jan. 1993 74 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-000073; NREL/TP-411-5289) Avail: CASI HC A04/MF A01

This report describes work to develop inverted-grown Al(0.34)Ga(0.66)As/GaAs cascades. Several significant developments are reported on as follows: (1) The AM1.5 1-sun total-area efficiency of the top Al(0.34)Ga(0.66)As cell for the cascade was improved from 11.3 to 13.2 percent (NREL measurement total-area). (2) The 'cycled' organometallic vapor phase epitaxy growth (OMVPE) was studied in detail utilizing a combination of characterization techniques including Hall-data, photoluminescence, and secondary ion mass spectroscopy. (3) A technique called eutectic-metal-bonding (EMB) was developed by strain-free mounting of thin GaAs-AlGaAs films (based on lattice-matched growth on Ge substrates and selective plasma etching of Ge substrates) onto Si carrier substrates. Minority-carrier lifetime in an EMB GaAs double-heterostructure was measured as high as 103 nsec, the highest lifetime report for a freestanding GaAs thin film. (4) A thin-film, inverted-grown GaAs cell with a 1-sun AM1.5 active-area efficiency of 20.3 percent was obtained. This cell was eutectic-metal-bonded onto Si. (5) A thin-film inverted-grown, Al(0.34)Ga(0.66)As/GaAs cascade with AM1.5 efficiency of 19.9 and 21 percent at 1-sun and 7-suns, respectively, was obtained. This represents an important milestone in the development of an AlGaAs/GaAs cascade by OMVPE utilizing a tunnel interconnect and demonstrates a proof-of-concept for the inverted-growth approach. DOE

TEST RESULTS OF A STIRLING ENGINE UTILIZING HEAT EXCHANGER MODULES WITH AN INTEGRAL HEAT PIPE
Robert C. Skupinski (Sverdrup Technology, Inc., Brook Park, OH.), Leonard K. Tower (Sverdrup Technology, Inc., Brook Park, OH.), Frank J. Madi (Sverdrup Technology, Inc., Brook Park, OH.), and Kevin D. Brusk Apr. 1993 13 p
(RTOP 590-13-11)
(NASA-TM-105883; E-7681; NAS 1.15:105883) Avail: CASI HC A03/MF A01

The Heat Pipe Stirling Engine (HP-1000), a free-piston Stirling engine incorporating three heat exchanger modules, each having a sodium filled heat pipe, has been tested at the NASA-Lewis Research Center as part of the Civil Space Technology Initiative (CSTI). The heat exchanger modules were designed to reduce the number of potential flow leak paths in the heat exchanger assembly and incorporate a heat pipe as the link between the heat source and the engine. An existing RE-1000 free-piston Stirling engine was modified to operate using the heat exchanger modules. This paper describes heat exchanger module and engine performance during baseline testing. Condenser temperature profiles, brake power, and efficiency are presented and discussed. Author

BASIC RESEARCH THERMOACOUSTIC HEAT TRANSPORT Annual Summary Report, 1 Oct. 1991 - 30 Sep. 1992
Anthony A. Atchley Nov. 1992 35 p
(AD-A261334; NPS-PH-93-006) Avail: CASI HC A03/MF A01

This annual report details progress in basic research in thermoacoustic heat transport made during the period October 1, 1991 through September 30, 1992. Our major research efforts were concentrated in two areas during FY92: (1) a standing wave analysis of the low amplitude performance of thermoacoustic prime movers both below and above the onset of self-oscillation and (2) a study of finite amplitude standing waves in both harmonic and anharmonic tubes. In addition to these areas, FY92 research efforts also included the investigation of heat driven refrigerators and preliminary work on investigations of thermoacoustic engines with laser Doppler anemometry. This technical report summarizes the important results of these projects. A publications, patents, presentations, and honors report is also included. DTIC

A COMPARISON OF THE WIND SYSTEM ATMOSPHERIC MODELS AND MATS DATA
Jerome D. Fast, Stephen Berman, and Robert P. Addis 14 Jul. 1992 15 p Presented at the 10th Symposium on Turbulence and Diffusion, Portland, OR, 29 Sep. - 2 Oct. 1992
(Contract DE-AC-9-89SR-18035)
(DE93-002687; WSRC-MS-92-178; CONF-9209158-9) Avail: CASI HC A03/MF A01

Atmospheric transport and diffusion models have been developed by the Environmental Technology Section (ETS) of the Savannah River Technology Center to calculate the location and concentration of toxic or radioactive materials during an accidental release at the Savannah River Site (SRS). The output from these models has been used to support initial on-site and off-site emergency response activities such as protective action decision making and field monitoring coordination. These atmospheric transport and diffusion models have been incorporated into an automated computer-based system called the Weather INformation and Display (WIND) System and linked to real-time meteorological and radiological monitoring instruments to provide timely information for these emergency response activities. This study will compare two of the WIND System atmospheric models, PUFF/PLUME and 2DPUF, with a select group of MATS experiments and examine the results in detail to determine the performance of the models. Additional results from this study can be found in Fast et al. DOE

AN ASSESSMENT OF ALTERNATIVES AND TECHNOLOGIES FOR REPLACING OZONE-DEPLETING SUBSTANCES AT DOE FACILITIES
C. W. Purcell, K. B. Miller, J. R. Friedman, R. D. Rapoport, D. R. Conover, P. L. Hendrickson, and T. C. Koss (Department of Energy, Richland, WA.) Oct. 1992 77 p
(Contract DE-AC-6-76RL-01830)
(DE93-002862; PNL-8222) Avail: CASI HC A05/MF A01

Title 6 of the Clean Air Act, as amended, mandates a production phase-out for ozone-depleting substances (ODSs). These requirements will have a significant impact on US Department of Energy (DOE) facilities. Currently, DOE uses ODS's in three major activities: fire suppression (halon), refrigeration and cooling (chlorofluorocarbons (CFC's)), and cleaning that requires solvents (CFC's, methyl chloroform, and carbon tetrachloride). This report provides basic information on methods and strategies to phase out use of ODS's at DOE facilities. DOE

AN INTRODUCTORY GUIDE TO UNCERTAINTY ANALYSIS IN ENVIRONMENTAL AND HEALTH RISK ASSESSMENT
F. O. Hoffman and J. S. Hammonds Oct. 1992 34 p
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00001)
(DE93-002873; ES/ER/TM-35) Avail: CASI HC A03/MF A01

To compensate for the potential for overly conservative estimates of risk, using standard US Environmental Protection Agency methods, an uncertainty analysis should be performed as an integral part of each risk assessment. Uncertainty analyses allow one to obtain quantitative results in the form of confidence intervals that will aid in decision making and will provide guidance for the acquisition of additional data. To perform an uncertainty analysis, one must frequently rely on subjective judgment in the absence of data to estimate the range and a probability distribution describing the extent of uncertainty about a true but unknown value for each parameter of interest. This information is formulated from professional judgment based on an extensive review of literature, analysis of the data, and interviews with experts. Various analytical and numerical techniques are available to allow statistical propagation of the uncertainty in the model parameters to a statement of uncertainty in the risk to a potentially exposed individual. Although analytical methods may be straightforward for relatively simple models, they rapidly become complicated for more involved risk assessments. Because of the tedious efforts required to mathematically derive analytical approaches to propagate uncertainty in complicated risk assessments, numerical methods such as Monte Carlo simulation should be employed. The primary objective of this report is to provide an introductory guide for performing uncertainty analysis in risk assessments being performed for Superfund sites. DOE

ATMOSPHERIC REACTIVE NITROGEN OXIDES AND THEIR RELATIONSHIP WITH URBAN AND RURAL OZONE FORMATION Ph.D. Thesis
Tao Wang 1992 230 p
Avail: Univ. Microfilms Order No. DA9303153

NO(x)(NO + NO2), HNO3, particulate NO3(-) and PAN are the primary forms of the reactive nitrogen oxides in the lower troposphere. NO(x) serves as catalyst and plays a key role in generating elevated ozone in the polluted boundary layer. PAN, HNO3, and NO3(-) are, like O3, the products of complex photochemistry involving hydrocarbons and nitrogen oxides. This work focuses on investigation of these nitrogen species in the ambient atmosphere of the southeastern U.S. including urban, suburban, and rural environments. These results indicate that for all environments encountered outside of the urban core, NO(x) is the limiting species in the formation of photochemical ozone. Dissert. Abstr.

USE OF THE ENVIRONMENTAL RESOURCE MANAGEMENT AND ANALYSIS SYSTEM AT THE FERNALD ENVIRONMENTAL MANAGEMENT PROJECT
J. L. Erjavec Jun. 1992 6 p Presented at the 104th Annual Meeting of the Geological Society of America, Inc., Cincinnati, OH, 26-29 Oct. 1992 Prepared in cooperation with Parsons Environmental Services, Inc., Fairfield, OH
(Contract DE-AC05-86OR-21600)
(DE93-002943; FEMP/SUB-052; CONF-921058-1) Avail: CASI HC A02/MF A01

In the past, hazardous waste site characterization and remediation using computer-based technologies has been a difficult and time-consuming process because of the need to analyze data using non-interfaced computer and software environments. The Environmental Resource Management and Analysis System (ERMA) was developed as an innovative approach to the management, analyses, and depiction of data collected during a hazardous site remediation. A modular, multi-disciplined software package, ERMA integrates an environmental database management system with a variety of Geographic Information System technologies. ERMA capabilities include spatial analysis, three-dimensional subsurface geologic interpretation and modeling, terrain modeling, and groundwater flow and contaminant transport modeling. ERMA's data management is provided through a set of user-modifiable, graphic interface tools that permit complex data queries,

data modification and reporting. An ERMA prototype has been implemented at the Fernald Environmental Management Project using groundwater monitoring and elevation data collected over the last few years. DOE

A NEW METHOD FOR INFRARED IMAGING OF AIR CURRENTS IN AND AROUND CRITICAL HAZARD FUME HOODS
William A. Mulac, James R. McCreary, and Henry Schmalz 1992 17 p Presented at the IAQ '92 Conference: Environments for People, San Francisco, CA, 18-21 Oct. 1992; sponsored by the American Society of Heating, Refrigerating and Air Conditioning Engineers, Inc.
(Contract W-31-109-eng-38)
(DE93-003009; ANL/CHM/CP-75284; CONF-921095-2) Avail: CASI HC A03/MF A01

A real-time method of measuring and recording the efficacy of vapor containment in and around critical hazard fume hoods is being developed. An infrared camera whose response is restricted to a spectral range that overlaps a strong absorption band in a non-toxic gas is used to render real-time video images of the presence and flow of the gas. The gas, nitrous oxide, is ejected in a continuous stream in and around fume hoods that are to be certified capable of containing hazardous fumes. The principle advantage is that various scenarios of air flow displacement in and outside the hood can be easily investigated; the principle limitation is the necessity of high tracer gas concentration to obtain strong visualizations. We hope that this technique can be found to be an effective and safe method to test hoods in locations that were built before present regulations were promulgated. DOE

ANALYSIS OF LARI SENSOR SYSTEM Final Report
Richard N. Pfisterer (Breault Research Organization, Tucson, AZ.), Gary L. Peterson (Breault Research Organization, Tucson, AZ.), and Robert P. Breault (Breault Research Organization, Tucson, AZ.) 25 Nov. 1992 18 p Prepared in cooperation with Breault Research Organization, Inc., Tucson, AZ
(Contract W-7405-eng-36)
(DE93-006334; LA-SUB-93-4) Avail: CASI HC A03/MF A01

Los Alamos National Labs (LANL) is developing a new space sensor for examination of global warming effects. This sensor is called LARI (Los Alamos Radiometric Instrument) and is a next generation follow-on to the ERBE instrument launched several years ago. Breault Research Organization, Inc. (BRO) is pleased to offer engineering consulting services for the development of this sensor. The goal of the consultation is to assist LANL engineers with the conceptual design of the LARI instrument. While the contract specifically stated that computer analyses would not be performed, we felt that some minimum level of computation effort would add more substance to the conclusions. DOE

AQUIS: A PC-BASED AIR INVENTORY AND PERMIT MANAGER
Albert E. Smith, Craig C. Huber, John Tschanz, and S. James Ryckman, Jr. (Air Force Materials Lab., Wright-Patterson AFB, OH.) 1992 8 p Presented at the International Symposium on Emission Inventory Issues and Progress, Research Triangle Park, NC, 19-22 Oct. 1992
(Contract W-31-109-eng-38)
(DE93-003006; ANL/EAIS/CP-77721; CONF-921060-1) Avail: CASI HC A02/MF A01

The Air Quality Utility Information System (AQUIS) was developed to calculate and track sources, emissions, stacks, permits, and related information. The system runs on IBM-compatible personal computers with dBASE 4 and tracks more than 1,200 data items distributed among various source categories. AQUIS is currently operating at nine US Air Force facilities that have up to 1,000 sources. The system provides a flexible reporting capability that permits users who are unfamiliar with database structure to design and prepare reports containing user-specified information. In addition to six criteria pollutants, AQUIS calculates compound-specific emissions and allows users to enter their own emission estimates. DOE

TRENDS '91: A COMPENDIUM OF DATA ON GLOBAL CHANGE. HIGHLIGHTS
Thomas A. Boden, ed., Robert J. Sepanski, ed., and Frederick W. Stoss, ed. Mar. 1992 71 p
(Contract DE-AC05-84OR-21400)
(DE93-003112; ORNL/CDIAC-49) Avail: CASI HC A04/MF A01

The Carbon Dioxide Information Analysis Center (CDIAC) at Oak Ridge National Laboratory (ORNL) was prompted to produce the series Trends, a concise inventory of data in response to heightened concern about global environmental issues, in particular climate changes induced by the greenhouse effect. Extracts from Trends '91 are presented to illustrate the content, style, and presentation of data contained in the full 700-page report. A listing of the investigators contributing data for Trends '91 is included. In addition, it contains the abstract, foreward, and acknowledgements, as well as the introduction and a sample data record from each of the reports's five chapters. The topics covered are atmospheric CO2, atmospheric CH4, other trace gases, CO2 emissions, and temperature. Appendix A provides information about CDIAC and its activities related to global environmental issues. Appendix B lists the contents of the full report. An order form for obtaining a free copy of Trends '91 is found in Appendix C. DOE

THE EFFECTS OF SAMPLING FREQUENCY ON THE CLIMATE STATISTICS OF THE ECMWF GENERAL CIRCULATION MODEL
Thomas J. Phillips, W. Lawrence Gates, and Klaus Arpe (Max-Planck-Inst. fuer Meteorologie, Hamburg, Germany.) Sep. 1992 26 p
(Contract W-7405-eng-48)
(DE93-003338; UCRL-ID-108226; PCMDI-5) Avail: CASI HC A03/MF A01

The effects of sampling frequency on the first- and second-moment statistics of selected European Center (EC) model variables are investigated in a simulation of 'perpetual July' with a diurnal cycle included and with surface and atmospheric fields saved at hourly intervals. The shortest characteristic time scales (as determined by the enfolding time of lagged autocorrelation functions) are those of ground heat fluxes and temperatures, precipitation and run-off, convective processes, cloud properties, and atmospheric vertical motion, while the longest time scales are exhibited by soil temperature and moisture, surface pressure, and atmospheric specific

humidity, temperature, and wind. The time scales of surface heat and momentum fluxes and of convective processes are substantially shorter over land than over the oceans. DOE

N93-25146# Lawrence Livermore National Lab., CA.
GLOBAL WARMING POTENTIAL FOR CF4
Donald J. Wuebbles and Allen S. Grossman 16 Nov. 1992 3 p
(Contract W-7405-eng-48)
(DE93-005740; UCRL-ID-112295) Avail: CASI HC A01/MF A01

With sufficient emissions, fluorinated gases such as CF4 could contribute significantly to the concerns about global warming because they are greenhouse gases, are chemically very inert, and have long accumulation lifetimes in the atmosphere. At this time, the only significant known source of CF4 is primary aluminum smelting. While current emissions are small, additional sources could make CF4 an important contribution to climate forcing in the future. DOE

N93-25147# Lawrence Livermore National Lab., CA.
A CORRELATED K-DISTRIBUTION MODEL OF THE HEATING RATES FOR H2O AND A MOLECULAR MIXTURE IN THE 0-2500 cm(EXP -1) WAVELENGTH REGION IN THE ATMOSPHERE BETWEEN 0 AND 60 km
Allen S. Grossman and Keith Grant 16 Nov. 1992 9 p
(Contract W-7405-eng-48)
(DE93-005741; UCRL-ID-112296) Avail: CASI HC A02/MF A01

A prototype infrared radiative transfer model using a correlated k-distribution technique to calculate the transmission between atmospheric levels was used to calculate the radiative fluxes and heating rates for H2O and a mixture of the major molecular absorbers in the atmosphere between 0 and 60 km. The mixture consists of H2O, CO2, O3, CH4, and N2O. The wave number range considered is 0-2500 cm(exp -1). The use of the k-distribution method allows 25 cm(exp -1) wave number bins to produce fluxes and heating rates which are within ten percent of the results of detailed line by line calculations. DOE

APPLICATIONS OF WAVELET-BASED COMPRESSION TO MULTIDIMENSIONAL EARTH SCIENCE DATA
J. N. Bradley and C. M. Brislawn 1993 13 p Presented at the 1993 Space and Earth Science Data Compression Workshop, Snowbird, UT, 2 Apr. 1993
(Contract W-7405-eng-36)
(DE93-007348; LA-UR-93-299; CONF-930490-1) Avail: CASI HC A03/MF A01

A data compression algorithm involving vector quantization (VQ) and the discrete wavelet transform (DWT) is applied to two different types of multidimensional digital earth-science data. The algorithm (WVQ) is optimized for each particular application through an optimization procedure that assigns VQ parameters to the wavelet transform subbands subject to constraints on compression ratio and encoding complexity. Preliminary results of compressing global ocean model data generated on a Thinking Machines CM-200 supercomputer are presented. The WVQ scheme is used in both a predictive and nonpredictive mode. Parameters generated by the optimization algorithm are reported, as are signal-to-noise ratio (SNR) measurements of actual quantized data. The problem of extrapolating hydrodynamic variables across the continental landmasses in order to compute the DWT on a rectangular grid is discussed. Results are also presented for compressing Landsat TM 7-band data using the WVQ scheme.The formulation of the optimization problem is presented along with SNR measurements of actual quantized data. Postprocessing applications are considered in which the seven spectral bands are clustered into 256 clusters using a k-means algorithm and analyzed using the Los Alamos multispectral data analysis program, SPECTRUM, both before and after being compressed using the WVQ program. DOE

CHAMMP
H. Abarbanel, R. Chervin, P. Colella, F. Dyson, S. Flatte, M. Freeman, M. Gregg, S. Koonin, C. Leith, and G. MacDonald et al Dec. 1992 57 p
(Contract DE-AI05-90ER-30174)
(DE93-007290; JSR-91-310) Avail: CASI HC A04/MF A01

The US global change research program embraces three important classes of activities. One is the long-term monitoring of climatic variables to detect and measure global change. A second class comprises detailed short-term studies of the processes that govern the climate system. The third activity involves the construction of climate models (e.g., ocean and atmospheric general circulation models - GCM's) incorporating the results of process studies to improve the ability to predict and eventually to respond to global change. The CHAMMP program clearly falls within the third class of activities (modeling) and complements DOE's Atmospheric Radiation Measurement Program (ARM) of process studies in the atmosphere, and NASA's Earth Observing System (EOS) program, aimed primarily at monitoring. CHAMMP's stated goal is to develop, verify, and

apply a new generation of climate model within a coordinated framework, that: (1) incorporates the best available scientific and numerical approaches to represent physical, biogeochemical, and ecological processes; (2) fully utilizes the hardware and software capabilities of new computer architectures; (3) probes the limits of climate predictability; and (4) can be used to address the challenging problem of understanding the greenhouse climate issue through the ability of models to simulate time-dependent climatic changes over extended times with regional resolution. WINTER WARMING FROM LARGE VOLCANIC ERUPTIONS
Alan Robock and Jianping Mao 1992 11 p
(Grant NAG5-1835)
(NASA-CR-192848; NAS 1.26:192848) Avail: CASI HC A03/MF A01

An examination of the Northern Hemisphere winter surface temperature patterns after the 12 largest volcanic eruptions from 1883-1992 shows warming over Eurasia and North America and cooling over the Middle East which are significant at the 95 percent level. This pattern is found in the first winter after tropical eruptions, in the first or second winter after midlatitude eruptions, and in the second winter after high latitude eruptions. The effects are independent of the hemisphere of the volcanoes. An enhanced zonal wind driven by heating of the tropical stratosphere by the volcanic aerosols is responsible for the regions of warming, while the cooling is caused by blocking of incoming sunlight. A STUDY OF MASS SIZE DISTRIBUTIONS AND PARTICLE DEPOSITION VELOCITIES IN AMBIENT AIR Ph.D. Thesis
Guor Cheng Fang 1992 233 p
Avail: Univ. Microfilms Order No. DA9301983

Atmospheric coarse, fine particle, and elemental (Al, Ca, Fe, Mg, Na, Si, Ti, Cd, Cr, Cu, Mn, Pb, V, Zn) mass-size distributions were measured with the Noll Rotary Impactor (NRI) and cascade impactor in Chicago, Illinois. Simultaneously dry deposition fluxes were measured with a smooth surrogate surface. The elements of crustal origin (Al, Ca, Fe, Mg, Na, Si, Ti) tend to associate with the coarse particle mode while the metals of anthropogenic origin (Cd, Cr, Cu, Mn, Pb, V, Zn) were associated with the fine particle mode. The data analyzed have shown that the concentration of heavy metals and particles exist in both fine and coarse ranges and that their distribution changed with wind direction. Samples taken with wind over Lake Michigan and lower concentrations than those with wind originating over the land. The mass deposition velocities for coarse and fine particles were calculated with a multiple regression method to be 6.0 and 0.50 cm/sec for the coarse and fine particles, respectively. Multiple regression method combined with Slinn and Slinn 1-step method yield 0.451 and 0.107 cn/sec deposition velocities for the coarse and fine particles. Using these methods of multiple regression it found that coarse particles are responsible for the majority (greater than 85 percent) of the dry deposition flux for the mass and all the elements. MEASUREMENTS OF NITRIC ACID, CARBOXYLIC ACIDS, AND SELECTED AEROSOL SPECIES FOR THE NASA/GTE PACIFIC MISSION - WEST (PEM-WEST) Final Report, 9 Apr. 1991 - 8 Apr. 1993
Robert W. Talbot and Jack E. Dibb Apr. 1993 27 p
(Grant NAG1-1233)
(NASA-CR-192976; NAS 1.26:192976) Avail: CASI HC A03/MF A01

The research investigation funded through this grant to the University of New Hampshire was performed during a major field expedition conducted by the NASA Tropospheric Chemistry Program. The NASA Global Tropospheric Experiment (GTE) executed an airborne science mission (PEM-WEST A) aboard the NASA Ames DC-8 over the Pacific Ocean during Sep./Oct. 1981. The atmosphere over the central Pacific Ocean is the only major region in the Northern Hemisphere that is relatively free from direct anthropogenic influence. Thus, this environment is ideally suited to study the natural biogeochemical cycles of carbon, nitrogen, ozone, sulfur, and aerosols without serious confounding problems related to anthropogenic emissions. Asian sources account for about 17 percent of the global budgets of nitrogen oxides (NO(x)) and sulfur dioxide (SO2). The Pacific Rim region therefore provides the opportunity to study the anthropogenic impact on natural atmospheric chemical cycles. The PEM-WEST A flights were focused on contrasting the chemistry of 'clean' air over the central Pacific with anthropogenically impacted air advected off the Asian continent. The principal objectives of PEM-WEST A were to investigate the atmospheric chemistry of ozone (O3) and its precursors, and to study important aspects of the atmospheric sulfur cycle over the western Pacific Ocean. Measurements conducted by the University of New Hampshire contributed directly to both of these objectives. Subsequent PEM-WEST field missions are planned by GTE in the mid-1990's to contrast atmospheric chemistry documented during PEM-WEST A with other time periods. This report presents preliminary findings from the PEM-WEST A field mission. Data interpretation is currently ongoing with the goal of manuscript submission of scientific results to a special issue of the Journal of Geophysical Research-Atmospheres in Feb. 1994. The reader is strongly encouraged to review this suite of profession articles to appreciate the overall scientific findings and benefits of the PEM-WEST A field mission. Derived from text

APPLICATION OF NON-THERMAL PLASMAS TO POLLUTION CONTROL
B. M. Penetrante, G. E. Vogtlin, J. N. Bardsley, P. A. Vitello, and P. H. Wallman Jan. 1993 12 p Presented at the 2nd International Plasma Symposium on World Progress in Plasma Applications, Palo Alto, CA, 9-11 Feb. 1993
(Contract W-7405-eng-48)
(DE93-007515; UCRL-JC-112689; CONF-930256-1) Avail: CASI HC A03/MF A01

Non-thermal plasma techniques can be used to destroy many types of hazardous molecules. They are particularly efficient when the toxic materials are present in very small concentrations. This paper discusses three particular applications of non-thermal plasmas: (1) decomposition of hydrogen sulfide (H2S); (2) removal of trichloroethylene (TCE); and (3) removal of nitric oxides (NO(x)). Emphasis is placed on the energy cost for implementing the decomposition or removal of these pollutants. Some of the factors affecting the energy cost are discussed. We discuss in detail our work at LLNL on pulsed plasma processing for the treatment of NO(x) in diesel engine exhaust. Our results suggest that our plasma reactor can remove up to 70 percent of NO(x) with relatively high initial concentrations (up to 500 ppM) at a power consumption cost of 2.5 percent for an engine with an output of 14 kW and an exhaust gas flow rate of 1200 liters per minute. KELVIN WAVES IN TOTAL COLUMN OZONE

J. R. Ziemke and J. L. Stanford Apr. 1993 10 p

(Grant NAG5-1519)

(NASA-CR-192984; NAS 1.26:192984) Avail: CASI HC A02/MF A01

Tropical Kelvin waves have been observed previously in ozone mixing ratio data from the SBUV (Solar Backscatter Ultraviolet) and LIMS (Limb Infrared Monitor of the Stratosphere) instruments on board the Nimbus-7 satellite. Kelvin wave features in total column ozone, using version 6 data from the Total Ozone Mapping Spectrometer (TOMS) instrument (also on board Nimbus-7) are investigated. Results show eastward-propagating zonal waves 1-2 with periods approximately 5-15 days, amplitudes approximately 3-5 DU, and latitudinal symmetry typical of Kelvin waves. A simplified model calculation suggests that the primary source for the perturbations is slow Kelvin waves in the lower-to-middle stratosphere. Maximum Kelvin wave signatures occur in conjunction with westward lower-to-middle stratospheric equatorial zonal winds (a quasi-biennial oscillation (QBO) wind modulation effect). Author (revised)

ROSSBY-GRAVITY WAVES IN TROPICAL TOTAL OZONE DATA

J. L. Stanford and J. R. Ziemke Mar. 1993 10 p

(Grant NAG5-1519)

(NASA-CR-192983; NAS 1.26:192983) Avail: CASI HC A02/MF A01

Evidence for Rossby-gravity waves in tropical data fields produced by the European Center for Medium Range Weather Forecasts (ECMWF) was recently reported. Similar features are observable in fields of total column ozone from the Total Ozone Mapping Spectrometer (TOMS) satellite instrument. The observed features are episodic, have zonal (east-west) wavelengths of 6,000-10,000 km, and oscillate with periods of 5-10 days. In accord with simple linear theory, the modes exhibit westward phase progression and eastward group velocity. The significance of finding Rossby-gravity waves in total ozone fields is that (1) the report of similar features in ECMWF tropical fields is corroborated with an independent data set and (2) the TOMS data set is demonstrated to possess surprising versatility and sensitivity to relatively smaller scale tropical phenomena. ENVIRONMENTAL RISKS AND FUTURE GENERATIONS: CRITERIA FOR PUBLIC POLICY

R. B. Howarth Oct. 1992 16 p Presented at the Conference on Clean Water and the American Economy, Arlington, VA, 19-21 Oct. 1992

(Contract DE-AC03-76SF-00098)

(DE93-004691; LBL-32993; CONF-9210256-1) Avail: CASI HC A03/MF A01

This paper examines alternative normative approaches to the policy challenges posed by long-term environmental problems such as toxic and radioactive waste disposal, stratospheric ozone depletion, and climate change. The paper argues that cost-benefit analysis is limited in its ability to handle the issues of intergenerational equity and uncertainty that are intrinsic to such problems. Also considered is the precautionary principle, which holds that policies should seek to reduce threats to the welfare of future generations if the costs of doing so would not significantly reduce the subjective well-being of existing persons. Although the precautionary principle depends on an explicit value judgement, it yields a policy criterion that is operationally decisive under a wide array of circumstances. DOE

EVALUATING CLIMATE-VEGETATION INTERACTIONS AT CLIMATE MODEL SUB-GRID SCALES Ph.D. Thesis

Katherine Margaret Klink 1992 165 p

Avail: Univ. Microfilms Order No. DA9301764

Land surfaces are an integral part of the global climate system, since most of the energy that drives the atmospheric circulation is absorbed and re-released from the surface of the earth. Terrestrial vegetation forms an important component of this surface because different vegetation types can significantly alter the character of the surface energy balance. In addition, vegetation characteristics are highly variable, both geographically and temporally. General circulation or global climate models (GCMs) that include a vegetation parameterization consider these properties to be homogeneous across large areas--typically 4 deg of latitude by 5 deg of longitude. These coarse-resolution characterizations seriously misrepresent the true heterogeneous nature of the earth's surface, and this introduces an additional (and largely unknown) degree of uncertainty into model results. To assess the role of surface heterogeneity at sub-GCM grid scales, a land-surface energy balance model is developed and is coupled to a mesoscale at atmospheric model. The land-surface model includes the effects on the surface energy balance of vegetation physical and physiological characteristics, as well as the influence of soil physical properties. This coupled system allows the surface and the atmosphere to be examined at the scale of a single GCM grid square. Two types of geographic surfaces were examined with the model. Each contained two different surface covers, either grass and bare soil, grass and deciduous trees, or grass and coniferous trees. In addition, both dry and moist soil environments were simulated. Model results showed that changes in vegetation geographic distribution resulted in differences in surface temperatures and evaporation amounts for each vegetation type as well as for the entire model domain. Maximum temperature differences ranged from 0.3 C to as much as 4 C over the course of the simulations, and latent heat flux differences were as large as 100 W m(exp -2). Differences in the nature and magnitude of the vertical velocities over each geographic surface were identified as the primary mechanism that produced these changes. Dissert. Abstr.

CLIMATE DATA BASES OF THE PEOPLE'S REPUBLIC OF CHINA, 1841-1988

Dale Kaiser, Shiyan Tao (Academia Sinica, Beijing, China.), Congbin Fu (Academia Sinica, Beijing, China.), Zhaomei Zeng (Academia Sinica, Beijing, China.), Qingyun Zhang (Academia Sinica, Beijing, China.), Wie-Chyung Wang (State Univ. of New York, Albany.), and Thomas Karl (National Climatic Data Center, Asheville, NC.) Jan. 1993 203 p Prepared in cooperation with Academia Sinica, Beijing, BJ (China); Inst. of Atmospheric Physics, State Univ. of New York, Albany, NY; Atmospheric Sciences Research Center, National Climatic Data Center, Asheville, NC

(Contract DE-AC05-84OR-21400)

(DE93-007907; DOE/NBB-0091T) Avail: CASI HC A10/MF A03

A data base containing meteorological observations from the People's Republic of China (PRC) is described. These data were compiled in accordance with a joint research agreement signed by the United States Department of Energy and the PRC Chinese Academy of Sciences (CAS) on 19 Aug. 1987. CAS's Institute of Atmospheric Physics (Beijing, PRC) has provided records from 296 stations, organized into five data sets: (1) a 60-station data set containing monthly measurements of barometric pressure, surface air temperature, precipitation amount, relative humidity, sunshine duration, cloud amount, wind direction and speed, and number of days with snow cover; (2) a 205-station data set containing monthly mean temperatures and monthly precipitation totals; (3) a 40-station subset of the 205-station data set containing monthly mean maximum and minimum temperatures and monthly extreme maximum and minimum temperatures; (4) a 180-station data set containing daily precipitation totals; and (5) a 147-station data set containing 10-day precipitation totals. Sixteen stations from these data sets (13 from the 60-station set and 3 from the 205-station set) have temperature and/or precipitation records that begin prior to 1900, whereas the remaining stations began observing in the early to mid-1900's.

Records from most stations extend through 1988. These data can be used in defining regional climate changes, establishing relationships between regional and large-scale climates, studying the climatic impacts of urbanization and increased concentrations of greenhouse gases, and in assembling large-scale climate data bases. Additional uses could include examining impacts of periodic events such as volcanic eruptions or the El Nino/Southern Oscillation. These data sets represent the most comprehensive, long-term instrumental Chinese climate data currently available. DOE

INVERSE SEQUENTIAL PROCEDURES FOR THE MONITORING OF TIME SERIES Progress Report No. 3

Uwe Radok and Timothy Brown 30 Apr. 1993 56 p

(Grant NAGw-2706)

(NASA-CR-192959; NAS 1.26:192959) Avail: CASI HC A04/MF A01

Climate changes traditionally have been detected from long series of observations and long after they happened. The 'inverse sequential' monitoring procedure is designed to detect changes as soon as they occur. Frequency distribution parameters are estimated both from the most recent existing set of observations and from the same set augmented by 1,2,...j new observations. Individual-value probability products ('likelihoods') are then calculated which yield probabilities for erroneously accepting the existing parameter(s) as valid for the augmented data set and vice versa. A parameter change is signaled when these probabilities (or a more convenient and robust compound 'no change' probability) show a progressive decrease. New parameters are then estimated from the new observations alone to restart the procedure. The detailed algebra is developed and tested for Gaussian means and variances, Poisson and chi-square means, and linear or exponential trends; a comprehensive and interactive Fortran program is provided in the appendix. AN ENVIRONMENTAL AUDIT MANAGEMENT PLAN FOR THE ROYAL AUSTRALIAN AIR FORCE M.S. Thesis

Warren L. Lear Sep. 1992 223 p

(AD-A261092; AFIT/GEE/CEV/92S-13) Avail: CASI HC A10/MF A03

The purpose of this research was to develop an Environmental Audit Management Plan (EAMP) tailored to meet the specific requirements of the Royal Australian Air Force (RAAF). The research also examined the resources which would be required to introduce the proposed EAMP into the RAAF. The literature on environmental compliance auditing identifies a number of essential characteristics required for an effective environmental auditing program. These characteristics, in conjunction with the USEPA design guidelines for the development of audit programs for government agencies, were used to guide the development of the RAAF EAMP. Information on Australian environmental legislation, DOD/RAAF policies and regulations, and details of the RAAF Base Tindal Environmental Management Plan were placed within this framework to produce the EAMP. The USAF Environmental Compliance Assessment and Management Program (ECAMP) was also used as a practical example of an existing audit management plan to provide further guidance in the preparation of the RAAF EAMP. To determine what would be required to implement the proposed EAMP, data on the implementation and operation of ECAMP was collected and analysed. From this, estimates of the resources required for the EAMP were prepared. DTIC

SMALL SATELLITES AND RPA'S IN GLOBAL-CHANGE RESEARCH

P. Banks, J. Cornwall, F. Dyson, N. Fortson, and R. Garwin 1 Dec. 1992 207 p

(AD-A260762; JSR-91-330) Avail: CASI HC A10/MF A03

This report contains an investigation of those global change science problems that can be addressed by remotely piloted aircraft or by small satellites, including the relationship to the NASA EOS program. New types of measurements that could be made possible by such satellite or aircraft platforms are pointed out. Issues of technical feasibility and cost are examined, as well as the role of new technology developed through DOD and other programs. Possible joint DOD/Global Science satellite missions are also discussed. DTIC

DEVELOPMENT OF A HEURISTIC KNOWLEDGE BASE FOR THE SELECTION OF APPLICABLE OR RELEVANT AND APPROPRIATE ENVIRONMENTAL REQUIREMENTS M.S. Thesis

Scott J. Borg and Gerald B. Puetz Sep. 1992 108 p

(AD-A261038; AFIT/GEE/CEC/92S-5) Avail: CASI HC A06/MF A02

Applicable or Relevant and Appropriate Requirements (ARAR's) are the basis used in establishing threshold limits for hazardous waste cleanups performed under the Comprehensive Environmental Response, Compensation and Liability Act (CERCIA). ARAR's selections must be applied consistently at numerous cleanup locations concurrently. The purpose of this research was to analyze activities required for the development of a heuristic knowledge base used for selection of ARAR's. The problem domain for the research was limited CERCLA cleanups of contaminated groundwater, through the use of a pump and treat strategy, using air stripping as the as the cleanup technology. The research examined literature concerning the importance of ARAR's in the CERCLA restoration process and the knowledge acquisition and representation methods. The research then analyzed the activities required to acquire and represent the knowledge required for the selection of ARAR's. A byproduct of the research was a proof-of-concept prototype expert system which was used to validate knowledge acquired and represented in the problem domain. Prototype validation included comparing the results of consultations with the expert system with ARAR's identified in the-Record of Decisions (ROD's) for actual CERCLA cleanups. In three of four cases, the expert system successfully identified all ARAR's germane to the cleanups. DTIC

REDISTRIBUTION OF TRACE CHEMICAL SPECIES BY A SMALL CONVECTIVE CLOUD

J. L. Stith, A. J. Alkezweeny, J. E. Pleim (Environmental Protection Agency, Research Triangle Park, NC.), and J. K. S. Ching (Environmental Protection Agency, Research Triangle Park, NC.) 1993 9 p Sponsored in part by EPA

(Contracts NOAA NA-17RA021801; NDARB-UND-NOAA91)

(PB93-156164; EPA/600/A-93/025) Avail: CASI HC A02/MF A01

The paper describes a new experiment with an SF6 tracer to determine the mixing history of a small region of cloud-base air. In situ measurements of the SF6 are made to follow the region, and simultaneous measurements of natural trace gases are used to determine the dilution of the tagged region as it is affected by the cloud. After describing the experimental method, the results from an experiment with a small cumulus, which was ideally suited for the experiment, are explained. The goal of the paper is to better understand how convective clouds redistribute trace constituents (e.g., moisture, trace gases) in the vertical. Author (DTIC)

POLLUTION PREVENTION 1991: PROGRESS ON REDUCING INDUSTRIAL POLLUTANTS

Sheila A. Ferguson, ed., Jo-Ann McNally, ed., Barbara F. Bass, Sarah E. Evans, Donna Churyk Huijing, Kathleen Matusik, Catherine G. Miller, Douglas C. Muir, Warren R. Muir, and Stephanie Murphy et al Oct. 1991 150 p

(PB93-157725; EPA-21P-3003) Avail: CASI HC A07/MF A02

Pollution Prevention 1991 is the first study to provide an overview of the range of activities in pollution prevention nationally. Its focus is on industrial pollution prevention where the greatest amount of activity has been occurring. The authors have tried to capture as many of the numerous activities that are underway within manufacturing facilities and in the policy discussions of government and citizens. The report briefly discusses the impact of pollution, prevention policies and programs for the consumer, agricultural, energy, and municipal sectors was well as for the conservation of significant resources, in future years the authors may see that these areas are a major focus of pollution prevention activities. QUALITY CONTROL: VARIABILITY IN PROTOCOLS

G. Y. Simes Sep. 1991 33 p

(PB93-157790; EPA/600/9-91/034) Avail: CASI HC A03/MF A01

The document Variability in Protocols (VIP) was initially designed as a quick reference for personnel performing QA audits, but it also has found its place in serving as a reference source for laboratory managers as well as personnel reviewing or developing QA Project Plans. Variability in Protocols contains tabular summaries of the quality control differences and similarities for some of the most frequently used analytical methods for water, soils, and other environmental samples. The document has been prepared in an attempt to bring together the separate methods that became a product of the major environmental statutes. Noticeable differences between methods are evidenced in method detection limits, calibration methods, blanks, spikes, and several other parameters included in the summary. The tabular format provides quick and easy access to important, needed information. VIP can provide guidance when preparing Quality Assurance Project Plans. Managers, field sampling team members, auditors, and laboratory personnel alike will find the document helpful in determining the most suitable method of chemical analysis for their various purposes. INCORPORATING BIODIVERSITY CONSIDERATIONS INTO ENVIRONMENTAL IMPACT ANALYSIS UNDER THE NATIONAL ENVIRONMENTAL POLICY ACT

Jan. 1993 40 p

(PB93-139806) Avail: CASI HC A03/MF A01

The report presents the results of consultations by the Council on Environmental Quality (CEQ) concerning the consideration of biological diversity in analyses prepared under the National Environmental Policy Act (NEPA). The report is intended to provide background on the emerging, complex subject of biodiversity, outline some general concepts that underlie biological diversity analysis and management, describe how the issue is currently addressed in NEPA analyses, and provide options for agencies undertaking NEPA analyses that consider biodiversity. The report does not establish new requirements for such analyses. It is not, and should not be viewed as, formal CEQ guidance on the matter, nor are the recommendations in the report intended to be legally binding. The report does not mean to suggest the biodiversity analyses should be included in every NEPA document, without regard to the degree of potential impact on biodiversity of the action under review. DEVELOPMENT AND DEMONSTRATION OF A NEW FILTER SYSTEM TO CONTROL EMISSIONS DURING JET ENGINE TESTING Final Report, Feb. 1990 - Sep. 1992

B. W. Nelson, D. A. VanStone, and S. G. Nelson 15 Oct. 1992 79 p

(Contract F08635-90-C-0053)

(AD-A261203; CEL-TR-92-49) Avail: CASI HC A05/MF A01

Measurable quantities of NO(x), CO and small particulates are produced and are emitted into the atmosphere during the testing of aircraft engines in jet engine test cells (JETC's). These emissions have been and are a concern to the Air Force and to others who test aircraft engines. The large quantities of exhaust gases that are generated, the wide range of testing conditions that are normally employed, and the sensitivity of engines to back pressures make control difficult and the use of conventional control technologies impractical. A need exists for a simple, low-cost method to control the emissions. In a Phase 1 SBIR project, Sorbent Technologies Corporation (Sorbtech) explored the ability of vermiculite to reduce or capture contaminants in exhaust gas streams. During the Phase 2 SBIR project described in this report, Sorbtech investigated how vermiculite might be employed in a commercial system to control emissions from JETC's and how chemical additions to vermiculite might enhance its NO(x)-removal abilities. The objectives of the Phase 11 project were to develop and to demonstrate a suitable filter design involving vermiculite that will control NO(x), CO, and small-particulate emissions during jet-engine testing. DTIC

SUMMARY BY THE CLOUD AND AEROSOL RESEARCH GROUP FOR ASTEX Final Report, 15 Apr. - 31 Dec. 1992

31 Dec. 1992 7 p

(Contract N00014-92-J-1587)

(AD-A261292) Avail: CASI HC A02/MF A01

Activity during the 1992 calendar year centered around the ASTEX project in the Azores and what has been, essentially, a small follow-up experiment conducted off of the Washington-Oregon coast, at least partially in conjunction with a series of test flights by the newly outfitted NRL blimp. The main experiment, conducted during ASTEX, had several objectives: (1) evaluate data for the occurrence of significant relationships between DMS, SO(2) SO equal 4 and CCN concentrations, (2) evaluate the strength of the relationship between boundary layer CCN concentration and cloud drop concentration in capping stratocumulus decks, (3) investigate the evolution of the particle size distribution in the boundary layer and (4) assess the effect of ship-induced aerosol flux on cloud dynamics and chemistry. The west coast experiment concentrated on only the fourth objective of the ASTEX study. A review of data reliability has been undertaken, and some preliminary data analysis as well. DTIC

USING TERRESTRIAL PLANTS IN BIOMONITORING

T. G. Pfleeger, H. C. Ratsch, and R. A. Shimabuku 1993 18 p Presented at the American Society Testing and Materials Second Symposium on Environmental Toxicology and Risk Assessment: Aquatic, Plant, and Terrestrial, Pittsburgh, PA, 26-30 Apr. 1993

(PB93-158780; EPA/600/A-93/029) Avail: CASI HC A03/MF A01

Visible foliar injury on Bell W-3 Tobacco was developed as an indicator of ozone pollution. The Tradescantia stamen hair system has been successfully used for a number of years as a monitor for chemical mutagenesis for air and water systems. However, plants have rarely been used as an indicator for chronic exposure to organic chemical pollutants. A test using Arabidopsis was developed for chronic root exposure to both metal and organic toxicants. A chronic shoot exposure test using a short life cycle Brassica was developed for monitoring aerial deposition of spray, fog, and gases. Preliminary work has begun on using terrestrial plants as biomonitors in detecting nontarget foliar injury from sulfonylurea herbicides. NTIS

AEROSPACE-PLANE FLIGHTS AND STRATOSPHERIC OZONE: REVIEW AND PRELIMINARY ASSESSMENT OF THE NATIONAL AEROSPACE PLANE (NASP) OPERATIONS
S. K. Liu 1992 63 p
(Contract F49620-91-C-0003)
(RAND/N-3464-AF) Avail: CASI HC A04/MF A01

The United States is now engaged in a major National Aerospace Plane (NASP) effort keyed to the goal of achieving low earth orbit using an air-breathing single-stage-to-orbit (SSTO) vehicle, the X-30. This goal requires meeting many sensitive technology and integration challenges. The NASP program management office fully recognizes these challenges and has mounted numerous concerted projects to achieve the required technology advances, in many instances accelerating progress substantially in fields several decades old. RAND undertook a study under sponsorship of Air Force's Directorate of Program Planning and Integration (SAF/AQX) to provide an integrated overview of the benefits, cost, and technical risks of potential NASP-derived vehicles (NDV). One task of this larger study was to examine some of the critical environmental aspects of the NASP program, specifically the effect of operational NDV's on stratospheric ozone and on noise intensity from sonic booms. The stratospheric ozone research and first-order estimates of the possible perturbation of water vapor and NOx content induced by the operation of the National Aerospace Plane (NASP) is reviewed. The primary purpose of this analysis is to assess the effect on stratospheric ozone from an operational fleet of NDV's.

HUMAN FACTORS IN ENVIRONMENTAL MANAGEMENT: NEW DIRECTIONS FROM THE HANFORD SITE
J. A. Wise and S. F. Savage Oct. 1992 7 p Presented at the Human Factors Society (HFS) Annual Meeting, Atlanta, GA, 12-16 Oct. 1992
(Contract DE-AC06-76RL-01830)
(DE93-004337; PNL-SA-21232; CONF-921048-7) Avail: CASI HC A02/MF A01

Environmental management is the general term given to modern attempts to seek technological solutions to certain constrained environmental problems. It involves developing and applying new technologies that respond to changes in environmental policy. It does not eliminate the need for 'environmental ethics' in society. Nor does it substitute for the fundamental changes in political and social structures that are needed for dealing with large-scale environmental issues. The scope of these issues can be illustrated by looking at the Hanford Site. Since 1943, the 560-square-mile Hanford Site in southeastern Washington state has been the production source of much of the nuclear weapons-grade radioactive materials for the United States. The legacy of 50 years of producing fissile materials has been an environmental cleanup problem of impressive proportions. In 1989, with the Cold War winding down, Secretary of Energy James Watkins established a new vision for Hanford as 'the flagship for waste management research.' As plans and preparations for cleanup work proceed at the Hanford Site and around the world, the need for well-orchestrated environmental management methodologies has become increasingly apparent. In 1990, a Human Factors Engineering Group was established in the Technology Planning and Analysis Center at PNL to provide appropriate support for the Laboratory's research efforts. At an ever-increasing rate, these research efforts require integrating human performance into complex environmental technology systems. The endeavor of responding to the Laboratory's research needs has provided innovative opportunities for the application of the concept of Human Factors. Discussed are some of the major applications of Human Factors to environmental management. DOE

RESPONSE AND FEEDBACKS OF FOREST ECOSYSTEMS TO GLOBAL CLIMATE CHANGE
R. K. Dixon 1993 16 p Presented at the 3rd Workshop on Closed Ecological Systems, Salt Lake City, UT See also PB91-104240 LIMITED REPRODUCIBILITY: More than 20% of this document may be affected by microfiche quality
(PB93-167252; EPA/600/A-93/049) Avail: CASI HC A03

The accumulation of greenhouse gases in the atmosphere over the past century is projected to cause a warming of the Earth. Climate change predictions vary by region and terrestrial biosphere response, and feedbacks will be ecosystem specific. Forests play a major role in the Earth's carbon cycle through assimilation of CO2, storage of carbon, and emission of greenhouse gases. Simulation models have been employed to examine the possible responses of global forest ecosystems to climate change. Major shifts in forest species distribution and composition are predicted in response to projected climate change within the next 50-80 years. The ultimate responses and feedbacks of forests will be influenced by the direction and magnitude of climate change, site quality and other stress agents.

INORGANIC NITROGEN AND PHOSPHORUS DYNAMICS IN THE WATER COLUMN OF THE PATUXENT RIVER Final Technical Report, 1 Jul. 1989 - 31 Dec. 1991
D. G. Capone, V. Miller, J. Love, and L. Duguay 1992 59 p LIMITED REPRODUCIBILITY: More than 20% of this document may be affected by microfiche quality
(Grant DI-14-08-0001-G1734)
(PB93-172955) Avail: CASI HC A04

An analysis was made of nitrogen (N) and phosphorus (P) dynamics in the water column of the Patuxent River, Maryland, over a 2 year cycle. Specifically, inorganic N and P assimilation were determined by isotopic tracer methods at 3 stations along the salinity gradient of the river on a monthly basis. The authors determined the concentrations of particulate N and P and the major dissolved species. Among inorganic species, nitrate showed the greatest seasonal variation, particularly at the upstream stations.

Nitrate, which increased going upstream, tended to dominate the inorganic N pools. Ammonium, nitrate and phosphate uptake varied over a wide range among and within sites. Values tended to increase moving upstream. Nitrate uptake dominated inorganic N assimilation upstream while ammonium uptake was of greater importance at the most saline station. With respect to indices of nutrient limitation, except for the summer, dissolved inorganic N was in excess relative to inorganic P, suggestive of P limitation. NTIS

IMPROVED SELECTIVE CATALYTIC NOx CONTROL TECHNOLOGY FOR COMPRESSOR STATION RECIPROCATING ENGINES Final Report, Sep. 1991 - Sep. 1992
C. E. Benson, K. R. Benedek, and P. J. Loftus Sep. 1992 89 p See also PB86-110186
(Contract GRI-5091-254-2235)
(PB93-158566; GRI-92/0364) Avail: CASI HC A05/MF A01

The objective of the program was to identify and assess improvements to Selective Catalytic Reduction (SCR) exhaust gas NO(x) control processes for stationary reciprocating engines at pipeline compressor stations. Based on commercial application experience in Europe and the U.S., it is evident that SCR systems have been successfully applied to control NO(x) emissions from natural gas fueled stationary engines. Nevertheless, cost, maintenance, and automation related aspects of most commercial SCR systems currently render the technology an unattractive NO(x) control option for pipeline compressor station engines. Desirable and feasible improvements to SCR technology were defined through interaction with technology consumers (pipeline companies) and technology suppliers (SCR manufacturers), followed by independent analyses. The key technologies recommended for advancement include: a non-extractive, continuous emissions monitoring system, integration and automation of optimized engine/SCR systems, engine NOx emission mapping and feed-forward control of the SCR process, and qualification and use of commercially available low phosphorus lubricating oils. Avail: CASI HC A06/MF A02

Measurements of oxides of nitrogen and carbon monoxide emission indices, flame radiant fractions, and visual flame dimensions were made for turbulent jet diffusion flames covering a wide range of test conditions. Parameters investigated included: initial jet velocity, jet diameter, fuel type, fuel dilution with inerts, partial premixing with air, and location and quantity of radial air injection. Detailed temperature measurements were also obtained for selected test conditions. The objectives of the study were (1) to develop a well-characterized data base to guide modeling efforts, and (2) to understand the relationships among NO(x) and CO emissions and flow conditions, fuel variables, and flame radiation. A major finding of the study was that the effects on NO(x) of residence time, flame temperature, and departure of the radical pool from equilibrium, whether caused by variations in initial jet velocity, jet diameter, fuel type, fuel dilution, or partial premixing, were well-characterized using two parameters: a characteristic nonadiabatic flame temperature, and a global residence time. Additional fuel-type dependencies, relating to the relative importance of prompt NO, were also found. NTIS

MODEL FOR TRANSPORT OF FLOATING DEBRIS IN THE OCEAN
Y. C. Su and E. R. Holley Feb. 1993 192 p Sponsored by Geological Survey, Reston, VA LIMITED REPRODUCIBILITY: More than 20% of this document may be affected by microfiche quality
(Grant DI-14-08-0001-G1728)
(PB93-172997; CRWR-236) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A model was developed to simulate the effects of wind, waves, ocean currents, and diffusion on the transport of floating debris in the ocean. Floating spheres with various sizes and specific gravities were considered in the applications. For advection, simulated wind profiles were established from previous experiments and were used with current velocities, water particle velocities computed from Stokes second-order wave theory, and gravitational settling on the inclined wave faces to determine the drag and added-mass for the spheres. The resulting unsteady force balance equations were solved numerically. When the advection became periodic, the time-averaged advective velocity of spheres was obtained. The cloud grows due to the combined effects of atmospheric and oceanic diffusion. A methodology based on statistics and diffusion theories was developed to yield approximate longitudinal and transverse diffusion coefficients which were used to obtain the size of the debris cloud. Several test cases showed that, except for very light floating objects, the transport is governed primarily by water drag. NTIS

(DE93-003789; LA-UR-92-3554; CONF-920967-1) Avail: CASI HC A03/MF A01

During the past two decades, interest in applying non-equilibrium plasmas to the removal of hazardous chemicals from gaseous media has been growing, in particular from heightened concerns over the pollution of our environment and a growing body of environmental regulations. At the Los Alamos National Laboratory, we are currently engaged in a project to develop non-equilibrium plasma technology for hazardous waste treatment. Our present focus is on dielectric-barrier discharges, which are historically called silent electrical discharges. This type of plasma is also named a silent discharge plasma (SDP). We have chosen this method due to its potential for high energy efficiency, its scientific and technological maturity, and its scalability. The SDP process has been demonstrated to be reliable and economical for the industrial-scale synthesis of ozone, where municipal water treatment plants frequently require the on-site generation of thousands of kilograins per day. The related methods of corona processing are presently the focus of work at other institutions, particularly for flue gas processing. Both SDP and corona processes are characterized by the production of large quantities of highly reactive free radicals, especially atomic oxygen O(3P) and the hydroxyl OH, in the gaseous medium and their subsequent reaction with contaminants. Our primary objective is to convert hazardous

or toxic chemicals into non-hazardous compounds or into materials which are more amenable to treatment. In the ideal case, the hazardous wastes are destructively oxidized to simpler, non-hazardous compounds plus CO2 and H2O. Sometimes the reaction products are still potentially hazardous, but are easily treated by conventional methods to yield non-hazardous products. DOE

In this study, a four-dimensional data assimilation technique based on Newtonian relaxation is incorporated into the Colorado State University (CSU) Regional Atmospheric Modeling System (RAMS) and evaluated using data taken from one experiment of the US Department of Energy's (DOE) 1991 Atmospheric Studies in COmplex Terrain (ASCOT) field study along the front range of the Rockies in Colorado. The main objective of this study is to determine the ability of the model to predict small-scale circulations influenced by terrain, such as drainage flows, and assess the impact of data assimilation on the numerical results. In contrast to previous studies in which the smallest horizontal grid spacing was 10 km and 8 km, data assimilation is applied in this study to domains with a horizontal grid spacing as small as 1 km. The prognostic forecasts made by RAMS are evaluated by comparing simulations that employ static initial conditions, with simulations that incorporate continuous data assimilation, and data assimilation for a fixed period of time (dynamic initialization). This paper will also elaborate on the application and limitation of the Newtonian relaxation technique in limited-area mesoscale models with a relatively small grid spacing. DOE

(Grant NAG1-804)
(NASA-CR-192834; NAS 1.26:192834) Avail: CASI HC A07/MF A02

The power spectrum for a stationary random process can be defined with the Wiener-Khintchine Theorem, which says that the power spectrum and the auto correlation function are a Fourier transform pair. To implement this theorem for signals that are discrete and of finite length we can use the Blackman-Tukey method. Blackman and Tukey (1958) show that a function w(tau), called a lag window, can be applied to the auto correlation estimates to obtain power spectrum estimates that are statistically stable. The Fourier transform of w(r) is called a spectral window. Typical choices for spectral windows show a distinct trade-off between the main lobe width and side lobe strength. A new idea for designing windows by taking linear combinations of the standard windows to produce hybrid windows was introduced by Smith (1985). We implement Smith's idea to obtain spectral windows with narrow main lobes and smaller (compared with typical windows) near side lobes. One of the main contributions of this thesis is that we show that Smith's problem is equivalent to a Quadratic Programming (QP) problem with linear equality and inequality constraints. A computer program was written to produce hybrid windows by setting up and solving the QP problem. We also developed and solved two variations of the original problem. The two variations involved changing the inequality constraints in both cases from non negativity on the combination coefficients to non negativity on the hybrid lag window itself. For the second variation, the window functions used to construct the hybrid window were changed to a frequency-variable set of truncated cosinusoids. A series of tests was run with the three computer programs to investigate the behavior of the hybrid spectral and lag windows. Emphasis was put on obtaining spectral windows with both relatively narrow main lobes and the lowest possible (for these algorithms) near side lobes. Some success was achieved for this goal. A 10 dB peak side lobe reduction over the rectangular spectral window without significant main lobe broadening was achieved. Also, average side lobe levels of -117 dB were reached at a cost of doubling the main lobe width (at the -3 dB point). Author

SURFACE ENERGY FLUXES AT CENTRAL FLORIDA DURING THE CONVECTION AND PRECIPITATION ELECTRIFICATION EXPERIMENT Final Report
D. Nie, T. D. Demetriades-Shah, and E. T. Kanemasu Apr. 1993 37 p
(Grant NAG8-910)
(NASA-CR-192826; NAS 1.26:192826) Avail: CASI HC A03/MF A01

One of the objectives of CaPE is to better understand the convective process in central and south Florida during the warm season. The energy and moisture exchanges between the surface and the atmosphere are closely related to this process. Some recent studies have shown that the surface energy balance plays an important role in the climatic fields (Shukla and Mintz, 1982; Sud and Smith, 1985; Sato et. al, 1989). Surface energy fluxes and related surface processes such as evapotranspiration and sensible heat transfer directly effect the temperature, humidity, cloud formation and precipitation. For example, mesoscale circulation around a discontinuity in vegetation type were shown to be stronger with wet soil than with dry soil using an evapotranspiration model (Pinty et. al, 1989). In order to better describe the processes in the atmosphere at various scales and improve our ability of modeling and predicting weather related events, it is crucial to understand the mechanism of surface energy transfer in relation to atmospheric events. Surface energy flux measurements are required to fully understand the interactions between the atmosphere and the surface. Derived from text

ANOMALOUS ASPECTS OF MAGNETOSHEATH FLOW AND OF THE SHAPE AND OSCILLATIONS OF THE MAGNETOPAUSE DURING AN INTERVAL OF STRONGLY NORTHWARD INTERPLANETARY MAGNETIC FIELD

Sheng-Hsien Chen, Margaret G. Kivelson, Jack T. Gosling (Los Alamos National Lab., NM.), Raymond T. Walker, and Allan J. Lazarus (Massachusetts Inst. of Tech., Cambridge.) 15 Sep. 1992 39 p

(Grant NAG5-1529)

(NASA-CR-192851; NAS 1.26:192851) Avail: CASI HC A03/MF A01

On 15 Feb. 1978, the orientation of the interplanetary magnetic field (IMF) remained steadily northward for more than 12 hours. The ISEE 1 and 2 spacecraft were located near apogee on the dawn side flank of the magnetotail. IMP 8 was almost symmetrically located in the magnetosheath on the dusk flank and IMP 7 was upstream in the solar wind. Using plasma and magnetic field data, we show the following: (1) the magnetosheath flow speed on the flanks of the magnetotail steadily exceeded the solar wind speed by 20 percent; (2) surface waves with approximately a 5-min period and very non-sinusoidal waveform were persistently present on the dawn magnetopause and waves of similar period were present in the dusk magnetosheath; and (3) the magnetotail ceased to flare at an antisunward distance of 15 R(sub E). We propose that the acceleration of the magnetosheath flow is achieved by magnetic tension in the draped field configuration for northward IMF and that the reduction of tail flaring is consistent with a decreased amount of open magnetic flux and a larger standoff distance of the subsolar magnetopause. Results of a three-dimensional magnetohydrodynamic simulation support this phenomenological model. Author (revised)

PARAMETRIC ANALYSIS OF ATMOSPHERIC PROCESSES Final Report

M. Elshamy 23 Apr. 1993 39 p

(Contract NAS8-36955)

(NASA-CR-192523; NAS 1.26:192523) Avail: CASI HC A03/MF A01

The different phases of the space shuttle mission operations and systems analyses are influenced by several random perturbations due to the dynamics of atmospheric processes. From the mission planning point of view, there are few atmospheric conditions of interest, such as thunderstorm, precipitation, cloud ceiling, peak surface wind speed, etc. These atmospheric conditions, called parametsrs, are actually constraints on the mission operations. An atmospheric parameter is a random variable which attains either a permissible or not permissible value. As such, each of these atmospheric parameters is assigned the values of either 0 or 1, for GO or NOGO outcomes, respectively. These atmospheric parameters are inherently dependent random variables. An important part of mission planning is being able to provide, ahead of time, a good assessment of GO/NOGO status for different atmospheric parameters as well as conditional probabilities involving GO and/or NOGO outcomes. Specifically, it is of interest to effectively address certain questions pertaining to the assigned constraints the different mission phases of the space vehicle. The questions of interest involve: (1) the probability that the assigned atmospheric constraints will (or will not) occur during a particular time; (2) the probability that the assigned atmospheric constraints will (or will not) occur for N consecutive days, at a particular time of the day; (3) given that the assigned constraints have occurred (or have not occurred) for n consecutive days, at a particular time of the day, what is the probability that the constraints will continue for N additional days?; (4) the probabilities of runs of GO and NOGO outcomes; and (5) estimating certain conditional probabilities involving GO and/or NOGO outcomes. Effectively addressing and giving specific answers to these types of questions are useful in many ways: (1) to determine design criteria for the space vehicle; (2) to establish flight operational rules; and (3) to set up effective cost assessments. The purpose of this technical report is to present an analytical study of the topics involved, such as the theories of runs and Markov chains, as well as an attempt to give answers to the questions raised above. We construct probabilistic models based on the nature of the problem, as well as certain assumptions relevant to atmospheric conditions. These models lay the ground work to establish a theory that would support a GO-NOGO decision. Author

DETERMINATION OF DESIGN AND OPERATION PARAMETERS FOR UPPER ATMOSPHERIC RESEARCH INSTRUMENTATION TO YIELD OPTIMUM RESOLUTION WITH DECONVOLUTION, APPENDIX 2 Final Report

George E. Ioup and Juliette W. Ioup Aug. 1988 122 p

(Grant NAG1-804)

(NASA-CR-192833; NAS 1.26:192833) Avail: CASI HC A06/MF A02

This thesis reviews the technique established to clear channels in the Power Spectral Estimate by applying linear combinations of well known window functions to the autocorrelation function. The need for windowing the auto correlation function is due to the fact that the true auto correlation is not generally used to obtain the Power Spectral Estimate. When applied, the windows serve to reduce the effect that modifies the auto correlation by truncating the data and possibly the autocorrelation has on the Power Spectral Estimate. It has been shown in previous work that a single channel has been cleared, allowing for the detection of a small peak in the presence of a large peak in the Power Spectral Estimate. The utility of this method is dependent on the robustness of it on different input situations. We extend the analysis in this paper, to include clearing up to three channels. We examine the relative positions of the spikes to each other and also the effect of taking different percentages of lags of the auto correlation in the Power Spectral Estimate. This method could have application wherever the Power Spectrum is used. An example of this is beam forming for source location, where a small target can be located next to a large target. Other possibilities extend into seismic data processing. As the method becomes more automated other applications may present themselves. Author

EMPIRICAL WIND MODEL FOR THE MIDDLE AND LOWER ATMOSPHERE. PART 1: LOCAL TIME AVERAGE

A. E. Hedin, E. L. Fleming (Applied Research Corp., Landover, MD.), A. H. Manson (Saskatchewan Univ., Saskatoon.), F. J. Schmidlin, S. K. Avery (Colorado Univ., Boulder.), and S. J. Franke (Illinois Univ., Urbana.) Apr. 1993 89 p

(RTOP 910-00-00)

(NASA-TM-104581; Rept-93B00069; NAS 1.15:104581) Avail: CASI HC A05/MF A01

The HWM90 thermospheric wind model was revised in the lower thermosphere and extended into the mesosphere and lower atmosphere to provide a single analytic model for calculating zonal and meridional wind profiles representative of the climatological average for various geophysical conditions. Gradient winds from CIRA-86 plus rocket soundings, incoherent scatter radar, MF radar, and meteor radar provide the data base and are supplemented by previous data driven model summaries. Low-order spherical harmonics and Fourier series are used to describe the major variations throughout the atmosphere including latitude, annual, semiannual, and longitude (stationary wave 1). The model represents a smoothed compromise between the data sources. Although agreement between various data sources is generally good, some systematic differences are noted, particularly near the mesopause. Root mean square differences between data and model are on the order of 15 m/s in the mesosphere and 10 m/s in the stratosphere for zonal wind, and 10 m/s and 4 m/s, respectively, for meridional wind. A STUDY OF ViBRATIONALLY EXCITED N2(+) IONS IN THE DAYTIME THERMOSPHERE Ph.D. Thesis

Lan-Sheng Hsu 1992 138 p

Avail: Univ. Microfilms Order No. DA9304232

The role of vibrationally excited N2(+) ions in the daytime thermosphere is studied. Ionization rates of the neutrals N2(+), O2(+), and O by solar extreme ultraviolet radiations with wavelengths below lambda 1050A and by impact of photoelectrons with energies between 10 to 500 eV are calculated. A photochemical model with ambipolar diffusion of ions included is used to obtain the altitude profiles of N2(+), O2(+), O(+), O(+)(P-2), O(+)(D-2), O2(+)(a(sup 4)pi(sub u)), NO(+), and N(+) ion densities. Vibrational level densities and vibrational distribution of the X(sup 2)((sigma(sub g)))(sup +), A(sup 2)pi(sub u), and B(sup 2)((sigma(sub u)))(sup +) electronic states of N2(+) ions are then calculated by taking into

consideration the direct ionization-excitation of N2(+) ions by solar extreme ultraviolet radiations and photoelectron impacts, fluorescent scattering of sunlight, chemical reactions, collision with neutrals, and radiative emissions. Column emission rates for the (0,0) band at lambda 3914A, (0,1) band at lambda 4277A, (1,2) band at lambda 4236A, an (2,3) band at lambda 4199A of the N2(+) first negative band system are then computed and compared with rocket flight data. Dissert. Abstr.

IMPROVED DETERMINATION OF VECTOR LITHOSPHERIC MAGNETIC ANOMALIES FROM MAGSAT DATA Final Report, 15 May 1992 - 31 Jan. 1993

Dhananjay Ravat Jan. 1993 59 p

(Grant NAG5-1972)

(NASA-CR-192784; NAS 1.26:192784) Avail: CASI HC A04/MF A01

Scientific contributions made in developing new methods to isolate and map vector magnetic anomalies from measurements made by Magsat are described. In addition to the objective of the proposal, the isolation and mapping of equatorial vector lithospheric Magsat anomalies, isolation of polar ionospheric fields during the period were also studied. Significant progress was also made in isolation of polar delta(Z) component and scalar anomalies as well as integration and synthesis of various techniques of removing equatorial and polar ionospheric effects. The significant contributions of this research are: (1) development of empirical/analytical techniques in modeling ionospheric fields in Magsat data and their removal from uncorrected anomalies to obtain better estimates of lithospheric anomalies (this task was accomplished for equatorial delta(X), delta(Z), and delta(B) component and polar delta(Z) and delta(B) component measurements; (2) integration of important processing techniques developed during the last decade with the newly developed technologies of ionospheric field modeling into an optimum processing scheme; and (3) implementation of the above processing scheme to map the most robust magnetic anomalies of the lithosphere (components as well as scalar). LOW-FREQUENCY SOURCE PARAMETERS OF TWELVE LARGE EARTHQUAKES M.S. Thesis

Paolo Harabaglia (Trieste Univ., Italy.) Jun. 1993 114 p

(Grants NAG5-549; NAGw-1905)

(NASA-CR-192806; NAS 1.26:192806) Copyright Avail: CASI HC A06/MF A02

A global survey of the low-frequency (1-21 mHz) source characteristics of large events are studied. We are particularly interested in events unusually enriched in low-frequency and in events with a short-term precursor. We model the source time function of 12 large earthquakes using teleseismic data at low frequency. For each event we retrieve the source amplitude spectrum in the frequency range between 1 and 21 mHz with the Silver and Jordan method and the phase-shift spectrum in the frequency range between 1 and 11 mHz with the Riedesel and Jordan method. We then model the source time function by fitting the two spectra. Two of these events, the 1980 Irpinia, Italy, and the 1983 Akita-Oki, Japan, are shallow-depth complex events that took place on multiple faults. In both cases the source time function has a length of about 100 seconds. By comparison Westaway and Jackson find 45 seconds for the Irpinia event and Houston and Kanamori about 50 seconds for the Akita-Oki earthquake. The three deep events and four of the seven intermediate-depth events are fast rupturing earthquakes. A single pulse is sufficient to model the source spectra in the frequency range of our interest. Two other intermediate-depth events have slower rupturing processes, characterized by a continuous energy release lasting for about 40 seconds. The last event is the intermediate-depth 1983 Peru-Ecuador earthquake. It was first recognized as a precursive event by Jordan. We model it with a smooth rupturing process starting about 2 minutes before the high frequency origin time superimposed to an impulsive source. Author (revised)

GEOLOGIC STRUCTURE AND PROCESSES OF THE EASTERN PACIFIC MARGIN: CALIFORNIA AND COSTA RICA Ph.D. Thesis

Kirk Duncan McIntosh 1992 181 p

Avail: Univ. Microfilms Order No. DA9235716

The margin of the eastern Pacific has been sculpted during Tertiary geologic times by convergent and transcurrent plate motion along both continental and oceanic plate boundaries. Interpretations of central California geology predict margin development by Early Tertiary plate convergence, the transition to a transform plate boundary, and subsequent modification of that boundary. Deep penetration seismic reflection transects (EDGE profiles) provide new data to refine these interpretations. These data support the interpretation that a plate fragment related to the Farallon plate may be continued to subduct off California after the Pacific/North America transform boundary was established to the north and south. These seismic data also reveal structures related to probable Miocene transtensional development of the offshore Santa Maria Basin after subduction eventually ceased in this area. The final stage of margin development is one of compressional deformation. This stage is documented by folding and thrust faulting, that appear to be concentrated near the zones of earlier extension and include examples of basin inversion. The Tertiary history of Costa Rica is one of plate convergence in an oceanic island arc setting. In particular, the plate boundary off the Nicoya Peninsula, Costa Rica, is an accretionary convergent margin in a low sediment supply environment. Seismic reflection data, including regional 2D profiles and a 3D survey over a portion of the lower trench slope, show mechanisms of sediment accretion, subsequent compressional deformation, and upper slope extension. The mechanisms of sediment accretion include offscraping at the trench, but the dominant process is underplating. With low sediment supply (no trench turbidites) the sedimentary cover on the subducting Cocos plate is thin and is accreted in small blocks. Variation in the basement structure of the Cocos plate perturbs the accretion processes and affects the arrangement of sedimentary blocks as they are accreted to the prism. The resulting prism structure varies rapidly along strike. The upper slope of the Costa Rica margin features an approximately 20 km wide zone of predominantly landward dipping normal faults. Seismic data show that the faults cut the entire 2 km thick slope apron section and penetrate the underlying accretionary prism. Dissert. Abstr.

ELASTIC MODELING AND MIGRATION IN EARTH MODELS Ph.D. Thesis

Carlos Alves FilhoCunha 1992 135 p

Avail: Univ. Microfilms Order No. DA9302197

Migration and inversion of marine seismic data using the elastic wave equation requires the transformation of the recorded pressure data into a vector particle-displacement field. This can be done easily when the recording geometry samples the wavefield both horizontally and vertically. However, only experimental surveys have cables located at different depths. Using a few assumptions, I derive a method for performing this transformation, which is applicable to standard surveys. The assumptions are: smooth water surface, cable nearly parallel to water surface, and perfect seismic-reflection at the water surface. Results in a realistic example, where these assumptions are only partially fulfilled, demonstrate that the method is robust. Elastic, reverse-time migration/inversion schemes in the space-time domain are usually implemented by finite-difference or finite-element methods. When imaging beyond structures, a dynamically accurate scheme must be used. For models characterized by layers with sharp boundaries, traditional finite-difference methods fail to correctly describe the dynamics of the propagation process. Failure comes from the lack of distinction between model and field variables; the same difference operator is applied to discontinuous (model) and continuous (wavefield) components. The problem is solved with a modified finite-difference scheme (dual-operator), which uses long operators for wave-fields, short operators for elastic parameters, Shoenberg-Muir (1989) equivalence relations, and a modified Virieux (1984) staggered grid scheme. Tests show that the dual-operator is dynamically more accurate than traditional finite-difference schemes and comparable to Haskell-Thomson schemes. In structurally complex media, accurate recovery of angle-dependent reflectivities requires elastic prestack migration. Mode separation can be done before or after depth extrapolation. Though more complex, the latter is more complete because it images mode-converted waves. Standard depth-extrapolation and imaging approaches are unsuitable for true-reflectivity recovery. I introduce an extrapolation method which properly compensates for transmission/conversion losses. This method is combined with an imaging condition that performs the plane-wave decomposition of the downward

extrapolated data to define the plane-wave-response (PWD) migration. The four image-cubes generated by the PWD migration correspond to the plane-wave angle-dependent reflectivities for PP, PS, SP, and SS modes, and directly relate to the Zoeppritz equations because they represent the in-depth plane-wave response of the medium. INTRAPLATE DEFORMATION, STRESS IN THE LITHOSPHERE AND THE DRIVING MECHANISM FOR PLATE MOTIONS Final Technical Report, period ending 31 Dec. 1991
Arden L. Albee 10 Mar. 1993 5 p
(Grant NAG5-842)
(NASA-CR-192782; NAS 1.26:192782) Avail: CASI HC A01/MF A01

The initial research proposed was to use the predictions of geodynamical models of mantle flow, combined with geodetic observations of intraplate strain and stress, to better constrain mantle convection and the driving mechanism for plate motions and deformation. It is only now that geodetic observations of intraplate strain are becoming sufficiently well resolved to make them useful for substantial geodynamical inference to be made. A model of flow in the mantle that explains almost 90 percent of the variance in the observed longwavelength nonhydrostatic geoid was developed.

THE ROLE OF MULTIPLE SCATTERING IN TWILIGHT ZENITH SKY OBSERVATIONS OF ATMOSPHERIC ABSORBERS: DIURNAL PHOTOCHEMISTRY AND AIRMASS FACTORS Ph.D. Thesis
Lori Mac Perliski 1992 186 p
Avail: Univ. Microfilms Order No. DA9304597

The ability to properly interpret UV-visible twilight absorption measurements of atmospheric chemical constituents is dependent on how well the optical path, or airmass factor, of light collected by the spectrometer is understood. In the case of direct light measurement, the airmass factor may be calculated from simple geometrical considerations for a spherical atmosphere. In the case of scattered light, a spherical radiative transfer model must be used. A simple single scattering model and a Monte Carlo radiative transfer scheme were developed to study the effects of multiple scattering, aerosol scattering, albedo and refraction on scattered light airmass factors. Stratospheric airmass factors are found to be relatively insensitive to multiple scattering, albedo, refraction and aerosol scattering by background aerosols at fairly short visible wavelengths (about 450 nm). Tropospheric airmass factors, on the other hand, are very sensitive to these processes. Ground albedo, refraction, multiple scattering and aerosol scattering are also important in determining photolysis rates of atmospheric species. It is found that one-dimensional photochemical model calculations of vertical column abundances of several stratospheric chemical constituents are relatively insensitive to changes in photolysis rates due to albedo, refraction and background aerosol scattering, although they are sensitive to multiple scattering. Following the June 1991 eruption of Mt. Pinatubo, OClO and BrO were observed at Fritz Peak Observatory for the first time every. The radiative and photochemical effects of the presence of Pinatubo volcanic aerosols are examined using a one-dimensional photochemical model coupled to a spherical matrix inversion radiative transfer model. Although the heterogeneous removal of NO(x) is not explicitly considered in the photochemical model, the photochemical effects of NO(x) removal may be studied by prescribing the amount of NO(x) removed by heterogeneous chemistry. Measured OClO and BrO column abundances are found to be consistent with model calculations of OClO and BrO column abundances for which 75-98 percent of NO(x) has been removed. Dissert. Abstr.

GRAVITY WAVES FROM O2 AIRGLOW Ph.D. Thesis
Shengpan Zhang 1991 281 p
Avail: Univ. Microfilms Order No. DANN70397

This thesis mainly consists of two parts: the method of data analysis for a new ground-based optical instrument MORTI which observes the O2 (0-1) airglow, and the theoretical interpretation of the results from the data collected by MORTI during the AIDA '89 campaign. Two algorithms of the data analysis have been developed. The first algorithm is a curve fitting method for calculating the rotational temperature with precision plus or minus K, the emission rate with precision plus or minus 5 percent, and the background continuum. Using this method, 22 nights of observation over Puerto Rico during April and May of 1989 were analyzed. The results show that the nightly average rotational temperatures were between 172K and 220K, and the nightly emission rates were between 271R and 917R. The second algorithm is for calculating the gravity wave parameters using the Lomb-Scargle method for unevenly spaced data. The horizontal wave direction and wave speed can be derived from the twelve-point measurements by MORTI. A total of fourteen gravity waves were found, two evanescent waves and twelve internal waves. The apparent wave periods of these waves were between 45 minutes and 360 minutes, their horizontal wavelengths were between 200 km and 2900 km, and the horizontal wave speeds were between 48 m/s and 282 m/s. The observed eta, the ratio of emission rate fluctuations to temperature fluctuations, were between 3.5 and 5.5, and temperature and emission rate fluctuations were generally in phase. The dependencies of eta on the wave parameters and chemical parameters are developed using a new model for the O2 airglow's response to a gravity wave. The model is in the Eulerian frame of reference using the traditional linearization and perturbation method. Two photochemical mechanisms, the three-body recombination and mechanism and the two-step transfer mechanism, and two kinds of waves, evanescent and internal, were separately discussed in detail. The predictions by this model agree with MORTI's observations fairly well, better than other available theoretical predictions. Both the measurements and the theory show the emission rate exhibits larger fluctuations than the temperature, and it is more reliable for detecting wave parameters and measuring airglow variation. The wave characteristics measured by MORTI are important for further study of the energy and moment transmission by waves in the mesopause region. Dissert. Abstr.

LOCAL AND REGIONAL ESTIMATES OF SENSIBLE AND LATENT HEAT FLUX DENSITIES FROM A PATCH-WORK SURFACE Ph.D. Thesis
Alan George Barr 1991 241 p
(ISBN-0-315-70882-4) Avail: Univ. Microfilms Order No. DANN70882

Regional, surface sensible and latent heat flux densities (H and LE) are important in climatology and hydrology. This study assesses the feasibility of estimating day-time H and LE from surface and upper-air weather data. The regional, upper-air estimates are compared with local, surface measurements above a surface patch-work of agricultural land and forest. Local surface H, LE and CO2 flux density were measured above nearby deciduous forest and alfalfa by the Bowen ratio method and eddy correlation (forest only). The day-time Bowen ratios (on average 0.15 forest and 0.17 alfalfa) and transpiration ratios (123 kg H2O kg(exp -1) CO2 forest and 135 kg H2O kg(exp -1) O2 alfalfa) were similar above forest and alfalfa. On some days, H averaged to near zero. Two approaches were used to estimate regional H and LE. The first used rawindsonde soundings of upper-air temperature and humidity. The second used an integral, convective boundary-layer (CBL) model, driven by surface temperature and humidity. Both approaches assumed that horizontal advection and subsidence were negligible, and that H and LE equalled the upper-air, integral storage changes of sensible and latent heat, integrated to well above the CBL.

THERMAL INFRARED RADIATION TRANSFER IN THE PLANETARY BOUNDARY LAYER Ph.D. Thesis
Wenzhong Zhao 1992 220 p
Avail: Univ. Microfilms Order No. DA9303846

A high spectral resolution thermal infrared radiation transfer program has been developed. It uses the emissivity growth method to calculate transmittances along in homogeneous paths from a line-by-line calculated database for homogeneous paths. This program offers high accuracy and reduces the computing time by about two orders of magnitude in comparison with the line-by-line method. Critical to the program are the choice of appropriate grid points for transmittance calculation, the double quadratic interpolation, and an appropriate stratification of the atmosphere. A criterion for evaluating grid points has been developed that can reduce interpolation errors significantly. This research reviewed and evaluated current measurements and theories on water vapor continuum absorption. By including the most current data, this radiation transfer program showed the significant effects of water vapor continuum absorption and produced

simulation results which agree with available measurements. The sensitivities of thermal radiation fluxes to a doubling of CO2 were significantly affected by the temperature and the water vapor profiles. Sensitivity studies also showed the extreme importance of the lower part of the boundary layer to the diurnal variation of the down-welling flux and the surface radiative energy budget. In the standard atmosphere, about 30 percent of the down-welling flux comes from the lowest 0.6 millibars and about 50 percent from the lowest 3 millibars. This research clearly showed that a widely used extrapolated profile cannot represent a daily average profile. The extrapolated profile overestimated the surface net radiation by 50 percent. A layer of fog was parameterized as a grey body for certain absorptions in radiation transfer simulations. The primary results of the one parameter model were consistent with observations. Dissert. Abstr.

A STATISTICAL STUDY OF FIELD-ALIGNED CURRENTS IN THE EARTH'S INNER MAGNETOSPHERE Ph.D. Thesis
Francis Keoki Chun 1992 406 p
Avail: Univ. Microfilms Order No. DA9301538

Field-aligned currents (FAC's) play a major role in the solar wind-magnetospheric interaction by electrodynamically coupling magnetospheric and ionospheric plasmas, so that stresses applied to the outer magnetospheric plasma are transmitted to the ionosphere and ultimately to the upper atmosphere. FAC's have been studied extensively since 1967 and all of our knowledge and understanding of this coupling mechanism is based on data from low altitude polar orbiting satellites. The purpose of this dissertation is to address some of the questions related to the persistence of magnetospheric FAC's during low levels of geomagnetic activity, their motion throughout the magnetosphere and their possible source mechanisms. We detrend and rotate ISEE-1 and 2 magnetometer data into a field-aligned coordinate system using the Tsyganenko (1987) magnetic field model in order to identify current sheet crossings. We calculate the properties of the FAC's to include their current intensity, density, velocity and thickness and discuss the technique used to extrapolate those properties to the ionosphere. We also determine the location and orientation of the FAC's as well as a measure of how closely they resemble sheets of current. We identify two types of FAC's in the magnetosphere; one that is quasi-stationary and another that is moving quickly so that it is observed simultaneously by the spacecraft. The quasi-stationary FAC's are magnetospheric extensions of the low altitude region 1 and 2 currents while the fast moving FAC's are possibly current carrying waves and/or transient phenomena. Both currents are highly responsive to geomagnetic activity with the fast moving currents responding strongly to high activity. During periods of quiet activity, magnetospheric FAC's are infrequently observed except for a region on the dusk night side from mid to high L-values suggesting that global convection does drive the dusk FAC's but that the three dimensional current system is non existent on the dawn side. We also examine the night side quasi-stationary FAC's with respect to substorm phase and find that when classified as a region 1 or 2 sense current, the night side region 2 currents are responsive to internal magnetospheric stresses due to night side reconnection whereas the night side region 1 currents are responsive to variations in the stress assiciated with both day side and night side reconnection. SOUNDING ROCKET OBSERVATIONS OF PRECIPITATING IONS IN THE MORNING AURORAL REGION Ph.D. Thesis
James Hart Clemmons 1992 142 p
Avail: Univ. Microfilms Order No. DA9304882

The origin of highly-structured ion fluxes measured by a sounding rocket launched into the morning auroral region on January 23, 1985 is investigated. The energy spectra of the precipitating ions exhibit an energy-time dependence in which particles of higher energies arrived at the rocket before those of lower energies. The spectra are interpreted as being due to the impulsive injection of particles onto high-altitude magnetic field lines, followed by their subsequent drift down the field lines to rocket altitudes. The dispersal to low energies with increasing time is explained as a time-of-flight effect in which the slower particles take longer times to traverse the distance. The ion signatures are used to constrain several possible physical models which characterize the source region. Source locations in the nightside magnetopause boundary layer are deduced through the examination of electron energy spectra and the use of a magnetospheric magnetic field model. The modeling efforts indicate that the data are consistent with sources located in the mid-latitude region of the flank boundary layer on the morning side of the magnetosphere, being in the range of 20-30 earth radii down the geomagnetic tail from the earth. Multiple injections of ions are observed, with a deduced quasi-periodicity of 100-200 s. Several candidate injection mechanisms are examined, with a mechanism related to the propagation of waves on the surface of the boundary layer found to be the most plausible explanation for the observations. Comparison is made to similar analyses by others and suggestions for future work are made. Dissert. Abstr.

THE PRESSURE MODULATION SYSTEM IN THE IMPROVED STRATOSPHERIC AND MESOSPHERIC SOUNDER Ph.D. Thesis
Peter Venters 1991 273 p
Avail: Univ. Microfilms Order No. BRD-97308

The technique of pressure modulation radiometry has been successfully used for the measurement of atmospheric pressures, temperatures and minor constituent amounts from orbiting spacecraft. This thesis describes the system used to effect the pressure modulation in the latest such instrument, the Improved Stratospheric and Mesospheric Sounder (ISAMS), which incorporates a number of further refinements to the technique. In particular, two matched pistons running in opposition are used to effect the modulation while considerably reducing the vibrational output of the mechanism. Considerable care has also been taken to design a chemically clean modulator, with no organic materials on the inside of the system. The dynamics of the double piston modulator are described, and simple approximations used to explain the main features of its behavior. In order to calculate the behavior of the gas in the modulator with sufficient accuracy to enable useful atmospheric measurements to be made, a detailed numerical model of the modulator was written. The predictions of the model were first validated against a comprehensive set of pressure cycle measurements made using a test modulator. Good agreement was obtained except for a modulator containing water vapor. It is shown that this discrepancy can be accounted for by the absorption of water vapor on the internal surfaces of the modulator. The performance of the modulators installed in the ISAMS is reviewed, and the numerical model used in the construction of an error analysis for the knowledge of the gas modulation. A preliminary discussion of the effects of these errors on the retrieval of atmospheric measurements is presented, and it is concluded that the prospects for the ISAMS to make a significant contribution to the understanding of the upper atmosphere are good. Dissert. Abstr.

AN INVESTIGATION OF THE ROLE OF FLUX DIVERGENCE IN THE TURBULENT KINETIC ENERGY BALANCE OF THE ATMOSPHERIC SURFACE LAYER Ph.D. Thesis
Christoph Alexander Vogel 1992 190 p
Avail. Univ. Microfilms Order No. DA9303151

The results of an investigation of the role of flux divergence contributions in the turbulent kinetic energy balance of the atmospheric surface layer are presented. Mechanisms of interest include the vertical divergence of the vertical turbulent flux of turbulent kinetic energy and the vertical divergence of the pressure-velocity covariance. Measurements for this analysis were made in a field experiment conducted in the fall of 1991 near Hay, New South Wales, Australia. Because the contributions of the pressure-velocity mechanism could not be measured directly, the effects of this term were determined as a residual in the TKE balance. All other terms in the governing equation were measured in the field. These included: the mechanical production of turbulence due to wind shear, the production (or damping) of turbulence due to buoyancy, the removal of turbulence due to viscous dissipation, and the redistribution of turbulence through the vertical divergence of the turbulent kinetic energy flux. The behavior of each of these mechanisms was determined over a range of stability and summarized in the form of an empirical function. As one result of this investigation, a significantly different behavior for the production of turbulence due to wind shear was found, thus defining an empirical relation more consistent with dimensional predictions. in addition, the behavior of the normalized viscous dissipation rate was found to be significantly different from the widely-accepted results of the Kansas experiments of the late 1960s. Further, the turbulence transport divergence was shown to remove turbulence at a significant rate in unstable conditions but to be negligibly

small in weakly stable conditions. The flux divergence of the pressure-velocity correlation was found to be an important source of turbulence in unstable conditions. Finally, one of the more significant results of this study was that the net contribution of the two flux divergence mechanisms was almost never negligible as had been previously assumed; that is, turbulence almost never dissipates locally in the atmospheric surface layer. Dissert. Abstr.

COMPUTATION OF MOISTURE FLUX FROM OCEAN TO ATMOSPHERE USING A SYNERGY OF SSM/I-DERIVED PRECIPITABLE WATER AND ECMWF ANALYSES Ph.D. Thesis
Charles Leslie Norris 1992 140 p
Avail: Univ. Microfilms Order No. DA9304590

Precipitable water (PW) measurements from the Special Sensor Microwave/Imager (SSM/I) are a source of atmospheric information that is not currently included in atmospheric analysis from the European Center for Medium Range Weather Forecasts (ECMWF). The SSM/I has better temporal and spatial coverage than other data sources which are currently used in ECMWF analyses. Estimates of ocean surface moisture flux (evaporation minus precipitation, or E-P) derived from a combination of SSM/I data and ECMWF analyses should be an improvement over estimates derived from ECMWF analyses alone. Surface moisture flux can be computed using the mass continuity equation for water vapor, which can be formulated in such a way as to take maximum advantage of precipitable water information. Three SSM/I-based PW algorithms from the current literature were tested against a statistically large set of radiosonde soundings to determine their suitability for global PW determination. Two of these algorithms were found to be acceptable for global PW computation, so final selection was based on convenience considerations. Daily maps of surface moisture flux were computed by solving the water vapor mass continuity equation for E-P for all areas receiving coverage by the SSM/I on two consecutive days. Daily flux maps for a one year period were then averaged together into monthly and annual means. Comparisons between the computed annual mean moisture flux and climatological estimates of E-P show good correlation. Differences between the computed annual mean and the climatology were of magnitude and distribution that would be expected due to interannual variability. Comparisons between monthly mean surface moisture flux and precipitation estimates show reasonable correlation, with areas receiving large amounts of precipitation generally showing strong negative moisture flux. Dissert. Abstr.

PARTICLE SIMULATION OF AURORAL DOUBLE LAYERS Ph.D. Thesis
Bruce Lee Smith 1992 166 p
Avail: Univ. Microfilms Order No. DA9230259

Externally driven magnetic reconnection has been proposed as a possible mechanism for production of auroral electrons during magnetic substorms. Fluid simulations of magnetic reconnection lead to strong plasma flows towards the increasing magnetic field of the earth. These plasma flows must generate large scale potential drops to preserve global charge neutrality. We have examined currentless injection of plasma along a dipole magnetic field into a bounded region using both analytic techniques and particle simulation. Our analysis shows that the maximum potential for cold ions and electrons, mass ratio m/M, is: q delta-V = K (1-m/M)/2 varies as mu delta-B, where mu is their common magnetic moment, K is the kinetic energy of the injected ions, and delta-B is the difference between the maximum magnetic field strength, B(MAX), and that at injection, B(sub 0). With thermal spread in particle magnetic moments the potential depends on their temperature ratios, T(i)/T(e), and with thermal injection velocities the magnetic field mirror ratio, B MAX/B(sub 0). An expression for the leading order potential for drifting isotropic Maxwellians is given. This potential is a boundary condition for the local field solution. While global charge neutrality must be maintained in steady-state, the local potential is determined by the Vlasov-Poisson equations. Several authors obtained quasineutral solutions (n(sub i) = n(sub e)) to this boundary value problem. However, single-valued quasineutral solutions are only accessible to special combinations of fields and particle distributions. In our case multivalued solutions to the quasineutral equation arise for particular values of electric and magnetic fields. A double layer is that solution which preserves gross quasineutrality within its volume while permitting momentum balance between incident accelerated particles. The potential of the double layer is limited by the ion kinetic energy but need not match the global potential required for overall charge neutrality. One and two dimensional electrostatic particle simulations verify both double layer solutions and dependence of potentials on the injected energy. The difference between global and local potentials is absorbed in a sheath opposite the injection boundary. Potential formations are strictly dependent on the self-consistent charge distributions they support. Microinstabilities cause changes in particle distributions. Double layer motion is associated with exchange of momentum between particles and these fields. Dissert. Abstr.

THEORETICAL STUDY OF TOPSIDE IONOSPHERIC CLUTTER Final Report, 28 Mar. 1990 - 27 Mar. 1992
Min-Chang Lee and Keith M. Groves 15 Jul. 1992 115 p
(Contract F19628-90-K-0024)
(AD-A260982; PL-TR-92-2162) Avail: CASI HC A06/MF A02

The sponsored research is aimed at understanding the small scale topside ionospheric plasma structures first observed at Millstone Hill, Massachusetts with the 440 MHz incoherent scatter radar. These small scale obliquely propagating plasma modes occurring in the vicinity of the mid-latitude ionospheric trough, have large radar cross-sections and narrow spectral widths. They have, until recently, been dismissed solely as hard target contamination of the incoherent scatter radar. The geophysical conditions associated with the ionospheric trough, such as the field aligned current activity and steep plasma density gradients, suggest that these recently discovered small scale topside ionospheric plasma structures may also appear in the auroral and polar regions. This speculation has been corroborated by our preliminary experiments and data analyses at Tromso, Norway and Sondrestromfjord, Greenland. Presented in this final report are our research results and Arecibo experiments simulating the geophysical conditions of generating these topside ionospheric plasma structures. Recommendation for the future research is also given. DTIC

JARE DATA REPORTS. NO. 171 (UPPER ATMOSPHERE PHYSICS 9). DATA, SYOWA AND ASUKA STATIONS, 1989
Akira Kadokura, Kunio Uchida, Noriyuki Kurihara, Kenichi Kimura, Hiroshi Okamura, Hidetoshi Ariyoshi (Nippon Electric Co. Ltd., Yokohama, Japan.), Akira Yukimatsu (Kyoto Univ., Japan.), Masaki Ejiri, ed., Takao Hoshiai, ed., and Takeo Hirasawa, ed. Feb. 1992 338 p
Avail: CASI HC A15/MF A03

This data book summarizes upper atmosphere physics data acquired by the Upper Atmosphere Physics Monitoring Systems at Syowa Station and Asuka Station in 1989. Observations were made at Syowa Station in the following areas: (1) geomagnetism; (2) ELF-VLF waves; (3) the ionosphere; and (4) auroras. The following are observation items from the

Asuka Station: (1) geomagnetism; (2) the ionosphere; and (3) the aurora. The Upper Atmosphere Physics Monitoring Systems were installed at Syowa Station in Jan. 1981 and at Asuka Station in Jan. 1987. An outline of the systems is given. Specifications of the observation instruments and the data acquisition systems are presented. The recording periods are also listed. The format of the compiled digital data is shown. Magnetograms and frequency-time spectra of magnetic pulsations in the period of 1 Jan. - 31 Dec. 1989 for Syowa Station and Asuka Station are given.

A PREDICTED GEOMAGNETIC FIELD MODEL FOR EPOCH 1990.0 Final Report
Malcolm G. McLeod Jan. 1993 18 p
(AD-A260669; NRL/FR/7442-92-9414) Avail: CASI HC A03/MF A01

An epoch 1990.0 geomagnetic field model will be produced by the Naval Oceanographic Office (NAVOCEANO) using magnetic field measurements from the recently launched (April 1990) Polar Orbiting Geomagnetic Survey satellite for part of the input data. To aid in the production and evaluation of this model, NAVOCEANO requested that the Naval Oceanographic and Atmospheric Research Laboratory (NOARL) develop a predicted field model for 1990.0. A predicted model of the geomagnetic field for epoch 1990.0 has been developed. The model is based on the Definitive Geomagnetic Reference Field (DGRF) model for 1980.0 updated to 1990.0 by use of a secular variation model for 1980.0 developed at NOARL. The NOARL secular variation model is based upon annual means of vector geomagnetic field components from 73 magnetic observatories for years 1976.5 through 1983.5. The predicted model is of spherical harmonic degree and order 10. The rms error of the predicted model is estimated to be 200 nT relative to an accurate degree 10 field model for epoch 1990.0. Peak errors relative to an accurate model are estimated to be 500 nT for vector field error magnitude and +/-350, +250, and +/-500 nT for north, east, and vertical field components errors, respectively. If the DGRF model for 1980.0 were used without updating to represent the degree 10 field for 1990.0, estimated errors would be about four times as large.

SAR-RELATED STRESS VARIABILITY IN THE MARINE ATMOSPHERIC BOUNDARY LAYER Final Report, 1 Jun. 1990 - 30 Sep. 1992
Hampton N. Shier and George S. Young 30 Sep. 1992 113 p
(Contract N00014-90-J-4012)
(AD-A261129) Avail: CASI HC A06/MF A02

Satellite- or aircraft-bourne synthetic aperture radars (SAR) have the potential to serve as a powerful and essential part of the global meteorological/oceanographic observation system. While the potential of SAR systems is enormous, quantitative interpretation of SAR signals has clearly been frustrated by our incomplete understanding of the relationships between the radar backscatter cross section and a complicated heterogeneous and constantly changing state of the sea surface. In the first phase of our High-Res ARI work summarized here, we began developing two new marine atmosphere boundary layer models of the surface stress caused by submesoscale boundary layer coherent structures and we finished obtaining plainview patterns of surface stress variability caused by MABL updrafts and downdrafts. We began turning our attention to such mesoscale atmospheric circulations as the solenoidal circulation over the sea surface temperature front, the coastal sea breeze circulation, and the flow between the Bermuda High and the diurnally varying pressure through on the coastal plain. In this report, we briefly review our progress on the work that will be continued and extended during the second phase of the project from October 1, 1992 to September 30, 1995. In Appendix A and Appendix B we give two manuscripts of journal articles summarizing our results. The first one by Sikora and Young (1993) discusses the plainview patterns of surface stress variability. The second one by Wells et al. (1993) discusses a new method for estimating the correlation dimension of boundary layer turbulent time series.

The final report for work on the determination of design and operation parameters for upper atmospheric research instrumentation to yield optimum resolution with deconvolution is presented. Papers and theses prepared during the research report period are included. Among all the research results reported, note should be made of the specific investigation of the determination of design and operation parameters for upper atmospheric research instrumentation to yield optimum resolution with deconvolution. A methodology was developed to determine design and operation parameters for error minimization when deconvolution is included in data analysis. An error surface is plotted versus the signal-to-noise ratio (SNR) and all parameters of interest. Instrumental characteristics will determine a curve in this space. The SNR and parameter values which give the projection from the curve to the surface, corresponding to the smallest value for the error, are the optimum values. These values are constrained by the curve and so will not necessarily correspond to an absolute minimum in the error surface.

IMAGING THE MAGNETOSPHERE IN THE EXTREME ULTRAVIOLET
Y. T. Chiu 6 Feb. 1993 38 p
(Contract NASw-4529)
(NASA-CR-192218; NAS 1.26:192218) Avail: CASI HC A03/MF A01

A final report on research on magnetosphere imaging in the extreme ultraviolet is presented. The objectives of the research contract can be summarized in three related items: (1) investigate the feasibility of the EUV imaging concept by using Lockheed in-situ ion measurement data; (2) investigate the technical resources required to make scientific interpretations of such EUV images by end-to-end simulations of the imaging concept; and (3) construct and test the key element for EUV magnetosphere imaging, the multilayer mirror with normal-incidence reflectance designed for the selected solar resonance line.

We have examined Sondrestrom incoherent-scatter radar observations of ionospheric plasma density and temperature distributions, as well as measurements of F-region ion drifts that were made during a prenoon pass by the DMSP-F7 satellite through the radar field of view. The spacecraft traversed a region of intense electron precipitation with a characteristic energy below approximately 200 eV. Particles with such low characteristic energies are believed to originate, either directly or indirectly, in the magnetosheath. The precipitation region had a width of about 2 deg invariant latitude. The corotating radar observed a patch of enhanced electron density and elevated electron temperature in the F2 region between about 10.5 and 12 magnetic local time in the same invariant latitude range where DMSP-F7 detected the soft-electron flux. The ion drift pattern, also obtained by radar, shows that it is unlikely that the plasma patch was produced by solar radiation and advected into the radar field of view. We suggest that the radar observed modifications of the ionospheric plasma distribution, which resulted from direct entry of magnetosheath electrons into the magnetosphere and down to ionospheric altitudes. Model calculations of the ionospheric response to the observed electron flux support our interpretation.

DIGITAL OBLIQUE REMOTE IONOSPHERIC SENSING (DORIS) PROGRAM DEVELOPMENT
Walter Kuklinski, Jon Hazelwood, and Bodo W. Reinisch Apr. 1992 46 p
(Contract F19628-90-K-0029)
(AD-A261750; PL-TR-92-2113; AD-E201414; SR-5) Avail: CASI HC A03/MF A01

The development and performance of a complete oblique ionogram autoscaling and inversion algorithm is presented. The inversion algorithm uses a three layer quasiparabolic model of the midpoint electron density profile. The inversion process is formulated as an optimization problem that uses a two-stage simulated annealing optimization algorithm. The inversion algorithm was tested using both synthetic data and oblique ionogram data obtained for a link between Goose Bay and Wallops Island. The results of the inversion were compared with midpoint electron density profiles recorded at the Maine OTH radar. DTIC

NONLINEAR WAVE PHENOMENA RELATED TO INTERACTIONS IN THE IONOSPHERE Final Report, 1 Sep. 1989 - 31 Aug. 1992
D. J. Kaup and A. S. Fokas 21 Jan. 1993 8 p
(Grant AF-AFOSR-0510-89)
(AD-A261450; AFOSR-93-0064TR) Avail: CASI HC A02/MF A01

A very important mechanism for the decay of upper hybrid waves into electron Bernstein waves was investigated. This mechanism operates only in a very narrow resonance region around the harmonics of the electron cyclotron frequency. The researchers calculated the width of these resonances and compared the analytical results with experimental observations. They found very good agreement with all available data. They found a simple mechanism for the generation of upper hybrid waves from the pump made by direct conversion. Simple estimates indicate how extremely large amplitude waves can be generated. DTIC

Avail: CASI HC A03/MF A01

The problem of estimating a steady fluid velocity field near the top of Earth's core which induces the secular variation (SV) indicated by models of the observed geomagnetic field is examined in the source-free mantle/frozen-flux core (SFI/VFFC) approximation. This inverse problem is non-linear because solutions of the forward problem are deterministically chaotic. The SFM/FFC approximation is inexact, and neither the models nor the observations they represent are either complete or perfect. A method is developed for solving the non-linear inverse motional induction problem posed by the hypothesis of (piecewise, statistically) steady core surface flow and the supposition of a complete initial geomagnetic condition. The method features iterative solution of the weighted, linearized least-squares problem and admits optional biases favoring surficially geostrophic flow and/or spatially simple flow. Two types of weights are advanced radial field weights for fitting the evolution of the broad-scale portion of the radial field component near Earth's surface implied by the models, and generalized weights for fitting the evolution of the broad-scale portion of the scalar potential specified by the models. A CHANNEL SIMULATION PROCESSOR FOR THE MULTI-NODE TACTICAL NETWORK SIMULATOR
Joseph P. Macker 17 Jan. 1993 27 p
(AD-A261810; NRL/MR/5523-93-7184) Avail: CASI HC A03/MF A01

The design and development of a digital signal processor (DSP) based groundwave and ionospheric communication channel simulator is described. The primary objective is to simulate communication channel perturbations for a network of communication via an array of DSP modules operating in real-time. This array of channel simulator processors is a subsystem of the multimode tactical network simulator (TACNETSIM) being developed by the Information Technology Division at the Naval Research Laboratory (NRL). The propagation model developed is based upon intra-battlegroup high frequency (HF) communications. The communication channel model consists of two modes of propagation: HF groundwave and HF skywave. The HF skywave component is simulated via a Watterson ionospheric model. The real-time DSP implementation of the Watterson ionospheric model is described in terms of subprocesses. The performance of each subprocess is shown to be within established statistical parameters. Detailed specifications are given of both the hardware and software design. The simulator is designed for dynamic channel modeling and includes a data interface for real-time program control. DTIC

CHAOS METRICS FOR TESTING LAGRANGIAN PARTICLE MODELS Technical Report, Mar. - Dec. 1992
R. F. Kamada 31 Jan. 1993 113 p
(AD-A261429; NPS-PH-93-007) Avail: CASI HC A06/MF A02

The Lorenz and Henon attractors and two atmospheric Lagrangian particle models were tested using self-affine fractal dimension, D(A), Shannon information entropy, S, and the Lyapunov exponent, lambda, along with turbulent kinetic energy, vertical variance, and Brunt-Vaisala Frequency. Results show that (1) chaos metrics are a new set of tools to assess the micro behavior of Lagrangian particle models. (2) that periodicity in bifurcatory systems differs from wave behavior in fluids, since wave states are not limited to amplitude extrema. (3) Non-spectral particle models lead to unrealistic variations in 'the chaos metrics with changes in buoyant stability. (4) S and D(A) behave oppositely at times, implying that diffusion and dispersion are not equivalent, even in the absence of mean windflow. DTIC

EFFECTS OF SURFACE THERMAL FORCING ON STRATIFIED FLOW PAST AN ISOLATED OBSTACLE Ph.D. Thesis - Iowa State Univ.
J. Reisner 1992 107 p Sponsored by NSF
(PB93-156776; NCAR/CT-140) Avail: CASI HC A06/MF A02

Scorer (1968) has pointed out that most experimental studies tend to overemphasize the effects of upstream stratification instead of the equally or perhaps more important effects of the localized heating and cooling of the surface of a three-dimensional (3-D) obstacle. Indeed, as shown, surface heating can lead to dramatic changes in the flow such as allowing for the disappearance of the upwind stagnation (defined as surface flow that is either zero or in opposite direction to the incoming flow). To understand how surface heating of mesoscale obstacles, such as the Hawaiian Archipelago, affects the flow, it is important to realize that heating will not only influence the surface flow but, perhaps more importantly, can also modify elevated flow structures such as internal gravity waves, columnar disturbances, and lee vortices. Basic aspects of the flow of a density-stratified fluid past three-dimensional obstacles for Froude number approximately O(1) and isolated surface thermal forcing representative of diurnally varying mesoscale flows past mountainous islands such as Hawaii are investigated. WEATHER FORECASTING EXPERT SYSTEM STUDY Final Report
Dec. 1985 165 p
(Contract NAS10-11333)
(NASA-CR-192929; NAS 1.26:192929) Avail: CASI HC A08/MF A02

Weather forecasting is critical to both the Space Transportation System (STS) ground operations and the launch/landing activities at NASA Kennedy Space Center (KSC). The current launch frequency places significant demands on the USAF weather forecasters at the Cape Canaveral Forecasting Facility (CCFF), who currently provide the weather forecasting for all STS operations. As launch frequency increases, KSC's weather forecasting problems will be great magnified. The single most important problem is the shortage of highly skilled forecasting personnel. The development of forecasting expertise is difficult and requires several years of experience. Frequent personnel changes within the forecasting staff jeopardize the accumulation and retention of experience-based weather forecasting expertise. The primary purpose of this project was to assess the feasibility of using Artificial Intelligence (AI) techniques to ameliorate this shortage of experts by capturing aria incorporating the forecasting knowledge of current expert forecasters into a Weather Forecasting Expert System (WFES) which would then be made available to less experienced duty forecasters. LAUNCH PAD LIGHTNING PROTECTION ENHANCEMENT BY INDUCED STREAMERS **c14**
James R. Stahmann (Boeing Aerospace Co., Cocoa Beach, FL.) and E. Ron Bentti *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 17 p (For primary document see N93-24875 09-47)
Avail: CASI HC A03/MF A03

Estimations of the effectiveness of launch pad lightning protection systems on protected points within the cone of protection usually ignore the effects of streamers that propagate out to meet down coming lightning leaders. Multiple streamers develop when the lightning leader is close enough to cause high electric fields and air breakdown on the structures. The tips of the streamers propagate toward the leader tip; and the longest and fastest streamers capture the stroke. Improved operational television at the launch pads has produced TV pictures of this process. The lightning protection enhancement caused by this streamer extension of the protective systems can be estimated. Author

LIGHTNING PRECURSOR SIGNATURES FROM DUAL-POLARIZATION RADAR MEASUREMENTS OF STORMS
Paul Krehbiel, Tiehan Chen, Stephen McCrary, William Rison, Grant Gray, and Marx Brook *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 6 p (For primary document see N93-24875 09-47)
(Grant AF-AFOSR-0450-89)
Avail: CASI HC A02/MF A03

Real-time correlation and display of the co-polar and cross-polar radar returns from electrically active storms has provided dramatic indications of the buildup of electric stress in the storms, and of the collapse of the stress at the time of lightning. Following up on the pioneering work of Hendry and McCormick, strong correlations are observed above the 0 degree C level in the middle and upper parts of storms that are indicative of the presence of electrically aligned particles. Regions of strong correlation are readily identified in scanning a storm and provide an excellent indicator of the potential for lightning in the storm. The correlation values have been used to predict the occurrence of individual lightning discharges in storms. In addition, they have been used to detect the onset of electrification in storms and to tell when a storm is finished producing lightning. Author

Kennedy Space Center (KSC) and the USAF Eastern Space Missile Center (ESMC) covering an area of 25 x 40 km are frequently called America's Spaceport. This title is earned through the integration, by labor and management, of many skills in a wide variety of engineering fields to solve many technical problems that occur during the launch processing of space vehicles. Weather is one of these problems, and although less frequent in time and duration when compared to engineering type problems, has caused costly and life threatening situations. This sensitivity to weather, especially lightning, was recognized in the very early pioneer days of space operations. The need to protect the many vfacilities, space flight hardware, and personnel from electrified clouds capable of producing lightning was a critical element in improving launch operations. A KSC lightning committee was formed and directed to improve lightning protection, detection, and measuring systems and required that all theoretical studies be confirmed by KSC field data. Over the years, there have been several lightning incidents involving flight vehicles during ground processing as well as launch. Subsequent investigations revealed the need to improve these systems as well as the knowledge of the electrical atmosphere and its effects on operations in regard to cost and safety. Presented here is how, KSC Atmospheric Science Field Laboratory (AFSL), in particular Rocket Triggered Lightning, is being used to solve these problems. Author

NUMERICAL MODELLING OF INDUCED EFFECTS OF LIGHTNING STRIKE ON AN ALL COMPOSITE HELICOPTER **c03**

Pascal Gondot, G. Donnet (Nucletudes, Montreuil, France.), and Patrick Trochet (Nucletudes, Montreuil, France.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 11 p (For primary document see N93-24875 09-47)

Avail: CASI HC A03/MF A03

The use of Carbon Fiber Composite in airframe construction arouses an increase of interest to protect sensitive avionic systems against indirect effects of lightning. In the SAE-AE4L recommendation, a long duration waveform is specified for equipment tests, especially in the case of an all composite structure. An all composite helicopter has been modeled with a FDTD method including internal structures and cables network. Then, the induced currents on shielded cables have been calculated for three lightning strike configurations. The purpose of this study is to discuss a specification for equipment tests based on calculations which permit us to distinguish typical waveforms and levels of transient for every equipment. Author

ZONING OF AIRCRAFT: A REVIEW OF THE DEFINITIONS **c03**

Nathaniel G. Bankston *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 16 p (For primary document see N93-24875 09-47)

Avail: CASI HC A03/MF A03

The assignment of lightning strike zones to the surface areas of aircraft is a necessary first step in the protection design and certification process. Lightning strike zones are defined with respect to an external environment that has been synthesized from the important characteristics of natural lightning. Based on recent discussions in the Society of Automotive Engineers (SAE) AE4-L committee on lightning standards, it is apparent that the zone definitions are not intuitively clear. This paper presents a review of the zone definitions and discusses some of the problems associated with these definitions, including the problem of making probability statements in the definitions. LIGHTNING DATA ACQUISITION

Rosemarie L. McDowall, J. Anderson Plumer (Lightning Technologies, Inc., Pittsfield, MA.), and Michael S. Glynn (Federal Aviation Administration, Atlanta, GA.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 7 p (For primary document see N93-24875 09-47)

Avail: CASI HC A02/MF A03

Three data collection programs are being pursued to acquire data which may be useful in the Federal Aviation Administration (FAA) lightning databases. The Commercial Lightning Database (CLD) program solicits lightning strike data from commercial and general aviation pilots via a form filled out by the pilot when his aircraft is struck. Current airline participants are American and Delta. Another source of data is the Bureau of Land Management (BLM) which runs a network of lightning sensors covering the 11 western states of the United States. Data on approximately 13 million strikes between 1985 and 1990 have been reviewed. In addition to these two sources, the Organization of Flying Adjusters (OFA) and the Aircraft Owners and Pilots Association (AOPA) are starting to supply data from their files. Author

A PROCEDURE FOR DEFINING LIGHTNING RISK TO AIR VEHICLES **c03**

David Beeman and Naomi Morita *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 18 p (For primary document see N93-24875 09-47)

Avail: CASI HC A03/MF A03

The risk of a lightning-induced failure is a function of the atmospheric conditions which produce lightning and the protective characteristics of the vehicle. Contemporary air vehicle designs - which incorporate 'wet' wings and extensive composite skin and structures - require thorough consideration of this risk to balance performance of lightning protection measures against other performance parameters (i.e., cost, weight, manufacturability, maintainability). An analytic procedure to investigate the risk of lightning-induced fuel vapor ignition is described in this paper. Sensitivity of the risk to various atmospheric and air vehicle design parameters was examined and is discussed. Author

PARAMETERS INFLUENCING THE HOT-SPOT IGNITION OF AVIATION FUEL/AIR AND ETHYLENE/AIR MIXTURES **c03**

Stephen J. Haigh and C. John Hardwick *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 9 p Sponsored by British Aerospace Aircraft Group; Civil Aviation Authority; Construcciones Aeronauticas S.A.; Dept. of Trade and Industry; Rolls-Royce Ltd.; Saab-Scania; and Short Bros. and

Harland Ltd. (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

Lightning attachments to aircraft skins can lead to the creation of local areas of heating or 'hotspots', which may be able to ignite fuel/air vapor mixtures contained within the skin. The characteristic temperature/time histories of such hot-spots are very different depending on whether the skins are metallic or carbon fiber. This report describes experimental work carried out under the Lightning Club program to determine the ability of transient hot-spots in metal foil to ignite JP4/air mixtures. The influence of parameters such as hot-spot size and duration is considered, as well as fuel concentration and oxygen enrichment. To establish the validity of simulation testing techniques in which ethylene is used to detect hotspots, some experiments are also carried out using mixtures of this gas with air. We make comparison of these with results with other reported work in this field. Author

COMPARISON OF THE ELECTRICAL CHARGING AND DISCHARGING ENVIRONMENTS OF MULTIPLE AIRCRAFT-BORNE ELECTRIC-FIELD MEASUREMENT SYSTEMS **c03**
Kathy L. Giori and J. E. Nanevicz *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 10 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

Various aircraft and particle charging and discharging mechanisms can adversely affect the performance of aircraft-borne electric-field measurement systems. Samples of data collected both during coordinated flight maneuvers (T-28 and SPTVAR aircraft) and from similar flight environments (Learjets 24B and 36A) have been analyzed and compared. These comparisons help in the identification and interpretation of the possible effects of (1) charged particles, and (2) aircraft charging and discharging phenomena on the respective electric-field measuring systems. It was found that the SPTVAR generally became more highly charged than the T-28, and the Learjet 36A more than the 24B. Such comparisons offer a better understanding of the electrical characteristics and of the measurement accuracies of these systems. Author

OBSERVATION OF RADIATION FROM LIGHTNING DISCHARGES BY LPATS
Masaru Ishii, Junichi Hojo, T. Yamamoto (Tokyo Electric Power Co., Inc., Japan.), E. Zaima (Tokyo Electric Power Co., Inc., Japan.), J. Sawada (Tokyo Electric Power Co., Inc., Japan.), and N. Fukiyama (Tokyo Electric Power Co., Inc., Japan.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 16 p (For primary document see N93-24875 09-47)
Avail: CASI HC A03/MF A03

A lightning location system known by the name of LPATS was installed on the central region of the Honshu Island as its third system in Japan. Calibration of the sensitivity of this system was completed in 1991, and a function to distinguish electromagnetic field waveforms having small peak-to-zero times was added at that time. By these modifications, the system has almost become able to distinguish negative cloud-to-ground strokes in summer, but still misinterprets many cloud-discharge pulses in summer as positive return strokes. Majority of such misinterpreted field waveforms had rather small range-normalized signal strengths, and were identified as bipolar pulses originating from cloud-discharge processes. In winter, such a difference depending on the polarity of return strokes becomes remarkably less, suggesting seasonal variation in the occurrence of cloud-discharge pulses. Author

A SYSTEM TO MEASURE LIGHTNING-INDUCED TRANSIENTS ON SPACECRAFT UMBILICAL LINES **c33**
Jeffrey C. Brown, Noel B. Sargent, and Carl J. Wenzler *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 8 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

Spacecraft electrical systems are potentially vulnerable during ground operations to damage from lightning-induced transients coupled onto umbilical cables. Limited data are available to compare spacecraft design protection levels with actual transient magnitudes. A system has been designed to accurately measure these transients and verify that spacecraft protection levels have not been exceeded. This paper describes the design and operation of the system and its installation at Launch Complex 36 on the Cape Canaveral Air Force Station (CCAFS). Author

A COMPUTATIONAL APPROACH TO PREDICTING THE EXTENT OF ARC ROOT DAMAGE IN CFC PANELS **c24**
Nicholas Jennings and C. John Hardwick (United Kingdom Atomic Energy Authority, Abingdon, England.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 8 p Sponsored in part by Rolls-Royce Ltd.; Construcciones Aeronauticas S.A.; Saab-Scania; Civil Aviation Authority; Dept. of Trade and Industry; and Short Bros. and Harland Ltd. (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

It is important to understand the mechanism of lightning arc root damage to carbon fiber composite panels in view of their increasing use in airframe construction. A computer model has been developed which contains coupled models of current and heat flow and predicts the extent of panel damage. Both initial stroke and continuing current components can be modelled, and the CFC parameters may be temperature dependent. Results and some comparisons with observations are presented. Author

COMPARISON OF THE DAMAGE FOR VARIOUS TYPES OF FIBRE REINFORCED COMPOSITES DUE TO DIFFERENT LIGHTNING TEST STANDARDS (MIL-STD-1757A, GERMAN MILITARY VG-STANDARD 96903) **c24**
Juergen Wiedmann, Jan-Uwe Roth, and Alexander W. Kern (Universitaet der Bundeswehr Muenchen, Neubiberg, Germany.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 16 p Sponsored by Ministry of Defence (For primary document see N93-24875 09-47)
Avail: CASI HC A03/MF A03

This paper provides experimental results on the extent and nature of damage on various types of aircraft FRC (fiber reinforced composites) caused by lightning arc attachment. Two different lightning test parameter sets were applied corresponding to MIL-STD-1757A and the German military VG-standard 96903 part 71. Concerning direct effects, the VG-standard differs from MIL-STD especially in the higher action integral (10 MJ/omega), the most important damage parameter with respect to FRC. Lightning tests with VG-standard are not known yet. The various types of tested aircraft FRC comprise unprotected and protected CFC and SFC/CFC-hybrid structures as well as novel, multilayered electromagnetic structures. The visible damage areas caused by impulse currents are strongly correlated to the action integrals. Metal protection meshes seem to suffer more from higher action integrals than the underlaying structures. The protection effectiveness of a new homogeneous protection system is proved. Author

LIGHTNING CHARACTERISTICS IN THE NORTH-EAST PART OF JAPAN OBSERVED BY A MAGNETIC DIRECTION-FINDER NETWORK
Noriyasu Honma, H. Komuro, Masaru Ishii (Tokyo Univ., Japan.), and Junichi Hojo (Tokyo Univ., Japan.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 10 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

Observations of lightning ground flashes have been made by a magnetic direction-finder network in the Tohoku region, located in the north-east part of the island of Honshu in Japan. The performance of this system has been evaluated and improved through close observations and ongoing analysis. Based on the data obtained to date, the density and the polarity of ground flashes were analyzed, focusing on various geographical and seasonal variations. It was concluded that the surrounding sea was the primary factor affecting ground flash characteristics. Author

FRACTAL DETERMINATION OF PARAMETERS IN LIGHTNING AND ESD MODEL **c32**
Giuseppe Vecchi, D. Labate, and F. Canavero *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 9 p (For primary document see N93-24875 09-47)
(Grant EEC-SC1-CT91-0690)
Avail: CASI HC A02/MF A03

In this paper, the radiation from a geometrically fractal (i.e., arbitrarily irregular) discharge channel is investigated from the point of view of fractal geometry. Numerical results are presented for lightning return stroke radiation, which demonstrate that the time waveform of radiated field (in the Fraunhofer region) is a fractal with the same fractal dimension as the channel path. Some implications of this finding are discussed. Author

ZONING OF AIRCRAFT BY ELECTRIC FIELD MODELLING **c03**
C. John Hardwick and V. K. Thompson *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 10 p Sponsored by British Aerospace Aircraft Group; Construcciones Aeronauticas S.A.; Rolls-Royce Ltd.; Saab-Scania; Short Bros. and Harland Ltd.; Westland Helicopters Ltd.; Civil Aviation Authority; and Dept. of Trade and Industry (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

The accurate determination of the zoning of aircraft has become more important with the increasing use of CFC materials in airframe construction. In-flight evidence suggests previous rules such as those given in the FAA AC20-53A are unsatisfactory. The proposed AC20-53B recommends substantially increased areas for Zone 1A. This paper presents an approach for calculating the initial attachment zones which, unlike the rolling sphere model, explicitly takes field concentration factors into account. Author

LIGHTNING PHENOMENOLOGY BASES FOR FULL THREAT RETURN STROKE OCCURRENCE FOLLOWING EXTENDED LEADER SWEEP AT FLIGHT ALTITUDES
J. Anderson Plumer *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 18 p (For primary document see N93-24875 09-47)
Avail: CASI HC A03/MF A03

It has been recognized that lightning leaders sweep aft from initial attachment points on aircraft forward extremities prior to arrival of the first return stroke, which, in a cloud-to-earth flash, is not initiated until a branch of the leader reaches the earth. This process has lead to more realistic procedures for locating lightning strike Zone 1A on aircraft surfaces, with the result that Zone 1A covers considerably more of the aircraft surfaces than previous zone location methods (i.e., 'the 18-inch criteria') would indicate. Some observers have suggested that, whereas the leader may indeed sweep a considerable distance alongside fast moving aircraft at flight altitudes, the intensity of the ensuing first return stroke will be less than it would be at the ground terminus of the lightning channel, because a portion of leader charge is below, not above, the airplane. Analytical models of lightning channels are often cited to support this, since such models often show reduction of the stroke intensity (i.e., peak current and action integral) with distance from the earth terminus. Physical damage on aircraft struck in flight belies this contention, however, as damage indicative of severe return strokes is often seen well beyond 18 inches aft of initial leader attachments. This paper discusses the natural lightning characteristics that explain why severe first return strokes may arrive well aft of forward extremity tips of aircraft, and why zone location methods must account for this. It is the third paper in a series begun in 1980 by the author on the topic of swept leader and zone location methodology, and presented at these conferences. Author

POSITIVE CLOUD-TO-GROUND FLASHES IN SEVERE STORMS
Donald R. MacGorman, Donald W. Burgess (National Weather Service, Norman, OK.), and Carolyn D. Morgenstern (Oklahoma Univ., Norman.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 8 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

We examine positive cloud-to-ground lightning in 25 mesoscale convective systems (MCS's) and in 15 severe storms. The signal amplitude distributions of positive ground flashes in MCS's that produced severe weather almost always either peaked at relatively large amplitudes or peaked at small amplitudes and decreased slowly with increasing amplitude. In the 15 severe storms we examined, cloud-to-ground flashes were dominated by positive flashes for periods ranging from 30 min to several hours. The geographic region in which positive or negative flashes dominated sequential storms on a given day appeared similar from storm to storm. In most cases observed by Doppler radar, storms dominated by positive flashes were low-precipitation or classic supercell storms. If negative ground flashes subsequently became dominant, the storm often became a classic or heavy-precipitation supercell storm. Large hail usually was reported during the period when positive ground flashes dominated, and the reported frequency and diameter of hail usually decreased after the dominant polarity of ground flashes switched to negative. In tornadic storms, the strongest tornado usually began after the positive ground flash rate decreased from its maximum value. Although many hailstorms and tornadic storms are dominated by negative flashes, tornadic storms and hailstorms comprise a small fraction of storms dominated by frequent negative flashes, but appear to comprise an overwhelming majority of storms dominated by frequent positive flashes. STUDY OF ATMOSPHERIC ELECTRICAL EVENTS ABOVE COMPLEX TERRAIN
Oscar Troncoso-Lozada *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 7 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

From the middle of 1982, there has been, in our institution, an interest in thunderstorm studies, aided greatly by advances in instrumentation and data processing. As a result, several cloud systems were analyzed and studied, and results are presented in this paper. The emphasis of the study was to investigate when and where the electrical discharge typically occur in relation to the lightning detection network. The sensor system consisted of two punctual discharge detectors, three radio noise detectors at frequencies of 10, 27, and 100 kHz, and a tipping-bucket rain-gauge adjacent to the sensors. The instrumentation used in this study has been described by Troncoso (1987). Author

APPLICATIONS OF STRESS ENVELOPE CONCEPTS TO AIRCRAFT EMP AND LIGHTNING SURVIVABILITY **c03**
Sam Frazier *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 6 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

The Naval Air Warfare Center Aircraft Division is conducting research into the modeling of aircraft electromagnetic transient response data. One result has been the development of a test point stress waveform which combines multiple responses. This single stress waveform bounds the test point stress responses collected during different test phases; each contributing waveform contains coupling response data from various polarizations, orientations, and configurations relative to the external threat environment. This new waveform, termed the 'Stress Envelope', has significant applications in the area of inductively coupled direct-drive, reducing test uncertainties, and permitting better estimates of system margins.

DEVELOPMENT OF MODELS FOR PREDICTING THE TRIGGERING OF LIGHTNING BY LAUNCH VEHICLES **c15**
Rodney A. Perala, Terence H. Rudolph, and Calvin C. Easterbrook *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 11 p (For primary document see N93-24875 09-47)
Avail: CASI HC A03/MF A03

As evidenced by incidents on Apollo 12 and AC-67 launches, the threat to launch vehicles from triggered lightning is real. Even in the absence of naturally occurring lightning, it is possible for a launch vehicle with attached plume to amplify atmospheric electric fields to an extent such that an electrical discharge can happen. Therefore, launch rules which are based on the presence of natural lightning in the vicinity may be inadequate to ensure that a triggered strike cannot occur. In order to develop adequate launch guidelines with respect to triggered lightning, it is necessary to first thoroughly understand the physical mechanisms leading to the triggered strike. To this end, we have begun to develop a triggered lightning model which will allow one to predict in advance the conditions under which a lightning strike will occur to a launch vehicle during ascent. The purpose of this paper is to describe the project and the technical issues, and to present some preliminary results. Author

COMMERCIAL PRECIPITATION STATIC (P-STATIC) TEST EQUIPMENT **c35**
R. Wayne Devereux *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 10 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

The aircraft industry requires commercially available, safe and reliable, test equipment to support Precipitation Static (P-static) Research, Development, Test and Evaluation (RDT&E). The test equipment must be able to simulate the in-flight P-static charging environment and acquire the P-static interference data for analysis of specification compliance. Using P-static test equipment, the aircraft industry can locate P-static problem areas, compare these results to specification limits, identify potential fixes, and evaluate fixes effectiveness. This paper describes the commercially available portable P-static test equipment designed, from a user's perspective, to meet the Royal Australian Navy's (RAN) aircraft ground support equipment's (GSE) needs. COMPARATIVE PERFORMANCE OF LIGHTNING AIR TERMINALS UNDER NATURAL STORM CONDITIONS
J. R. Gumley and Philip J. Jones (Lightning Protection International Proprietary Ltd., Hobart, Australia.) *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 7 p (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

During August 1992, a test site was established in Florida to assess the upward leader initiation capability of air terminals under natural storm conditions. Five types of air terminals were mounted independently on 10 m masts and grounded through one ohm resistors to sense emission currents. Two terminals were corona forming types, and three were spherical in design. Coaxial feeders conveyed the derived voltages to digitizer cards located in a personal computer with hard disc and tape drive storage. The two types of events described were recorded from very close lightning. The first showed marked differences in the emission currents of the spherical and corona forming terminals at the commencement of the return stroke. The latter exhibited strong negative polarity while the 3 spheres simultaneously produced a strong positive deflection. Several events displayed this type of characteristic. The second type of event recorded pulse currents of 10-15 amperes with polarity consistent to that expected for upward streamer initiation. These emissions were generated from the floating spheres 30-150 microseconds ahead of the return stroke. No significant or similar emissions were recorded in the same period from the conventional sphere or from the Franklin Rod. The reference Franklin Rod showed the lowest predischarge activity in 75 percent of recorded events. Author

ALTERNATIVE EQUIPMENT TEST PROCEDURES FOR SIMULTANEOUS CURRENT INJECTION ON MULTIPLE CABLE BUNDLES **c33**
C. John Hardwick, Stephen J. Haigh, and R. E. Baldwin *In* FAA, The 1992 International Aerospace and Ground Conference on Lightning and Static Electricity: Addendum Nov. 1992 9 p Sponsored by British Aerospace Aircraft Group; Civil Aviation Authority; Construcciones Aeronauticas S. A.; Dept. of Trade and Industry; Rolls-Royce Ltd.; Saab-Scania; and Short Bros. and Harland Ltd. (For primary document see N93-24875 09-47)
Avail: CASI HC A02/MF A03

Simple equipment tests can be accomplished by injecting currents into interconnect cables and adjusting the voltage injected into the loop under test or current in the cable until the ETDL is reached. However, for more complicated systems with several cables, this simple procedure is inadequate. This paper compares measurements made on cable bundles in a fuselage with both injection into the fuselage and injection on bundles to illustrate the problem and proposes alternative test methods. A SYSTEMATIC SATELLITE APPROACH FOR ESTIMATING CENTRAL PRESSURES OF MID-LATTITUDE OCEANIC STORMS
Frank J. Smigielski and H. Michael Mogil Dec. 1992 71 p
(NOAA-TR-NESDIS-63) Avail: CASI HC A04/MF A01

The development and applications of the Smigielski-Mogil-Burtt technique, used to assess central pressures of mid-latitude Atlantic Ocean cyclones are described. The technique combines attributes of the Junker-Haller technique (1980) and Dvorak tropical cyclone analysis technique (1984) in a flow chart format. It is based on the analysis of 50 full-latitude cyclone developments during the colder months, as well as operational feedback provided by National Weather Service and the U.S. Navy forecasters. The paper was also written to supplement training courses conducted by the authors. Forecasters should read the background material in the first four sections before completing the case to make independent assessments on a storm's central pressure before finding out 'solutions.' Author (revised)

THE CHARGE AND SIZE OF PRECIPITATION PARTICLES INSIDE THUNDERSTORMS AND MESOSCALE CONVECTIVE SYSTEMS ON THE GREAT PLAINS Ph.D. Thesis
Monte Gene Bateman 1992 154 p
Avail: Univ. Microfilms Order No. DA9305953

We created a new balloon-borne instrument that measures the charge (q) and size (d) of precipitation particles; we call it the q-d instrument. It is capable of measuring particle sizes ranging from 0.8 to 8.0 mm diameter

and charges ranging from plus or minus 4 to plus or minus 400 pC. The q-d instruments were flown into thunderstorms and mesoscale convective systems. We did not find any dependence of precipitation charge on ambient thermodynamic or electrical conditions. Both polarities of charge were found to coexist at nearly all altitudes within and below most storms. The exception was that only particles with positive and no detectable charge were measured within and below a decaying thunderstorm. The fraction of all particles that carried no detectable charge ranged from 17-77 percent and did not depend on the magnitude of the vertical electric field. We found evidence of positive charging by melting. When we compared the charge density due to precipitation with the total charge density calculated from the vertical electric field profile using Gauss's law, we found the former to be a factor of 2-100 smaller. This implies that much charge was carried on particles smaller than 0.8 mm diameter. Dissert. Abstr.

CLOUD PROPERTIES AS INFERRED FROM HIRS/2 MULTI-SPECTRAL DATA Ph.D. Thesis
Eric Otto Schmidt 1991 156 p
Avail: Univ. Microfilms Order No. DA9238476

Cloud properties and types are inferred from analysis of the 3.74 micron, 6.7 micron, and 11.1 micron data from the HIRS/2 instrument. The data analyzed was recorded on September 14 and 15, 1988 in the Ohio valley area. The approach uniquely uses the 6.7 micron water vapor channel data to improve detection of clouds by exploring discrimination between high and low clouds. Information on cloud height, cloud fraction, and emissivity is determined from the Baum multi-spectral multi-resolution (MSMR) method and used in determination of cloud optical depth and type. Improved identification of cloudy pixels by the MSMR method is a feature of the technique, as is the application of a brightness temperature difference comparison for the 6.7 micron and 11.1 micron channels. Multi-spectral image classification supports the presence of clouds, including subvisual cirrus, for these two days. The spectral classification and analyses incorporate the AVHRR GAC data at 3.74 microns, 10.8 microns, and 12.0 microns, while the MSMR method also utilizes HIRS/2 CO2 and infrared window channels. All cloud types in the image are identified and their optical properties (optical depth, cloud-top pressure height, emissivity, cloud fraction, and cloud-top equivalent brightness temperature) determined. Comparison of the spectral data with radiative transfer model results establishes limits on determinable cloud parameters and suggests further study of the effects of multiple layers in complex cloud systems.

INITIALIZATION OF A MODELED CONVECTIVE STORM USING DOPPLER RADAR-DERIVED FIELDS Ph.D. Thesis
Ying Lin 1992 125 p
Avail: Univ. Microfilms Order No. DA9306039

A method is developed to initialize convective storm simulations with Doppler radar-derived fields. Input fields for initialization include velocity, rain water derived from radar reflectivity, and pressure and temperature fields obtained through thermodynamic retrieval. A procedure has been developed to fill in missing wind data, followed by a variational adjustment to the filled wind field to minimize 'shocks' that would otherwise cause the simulated fields to deteriorate rapidly. A series of experiments using data from a simulated storm establishes the feasibility of the initialization method. Multiple Doppler radar observations from the 20 May 1977 Del City tornadic storm are used for the initialization experiments. Simulation results initialized from observations taken at two different stages of storm development are shown and compared to observations taken at later times. A simulation initialized from one of the observation times showed good agreement with subsequent observations, though the simulated storm appeared to be evolving much faster than observed. Possible mechanisms for error growth are discussed. Dissert. Abstr.

A DYNAMICAL THEORY FOR HURRICANE SPIRAL BANDS Ph.D. Thesis
Thomas Alan Guinn 1992 190 p
Avail: Univ. Microfilms Order No. DA9303868

A dynamical theory is presented for two classes of hurricane spiral bands--inner and outer. Inner bands, which typically form within 500 km of the vortex center, can result from both potential vorticity (PV) wave breaking and vortex merger. PV wave breaking is found to occur when the PV field is asymmetric. This process ejects a relatively high PV air down gradient into regions of relatively low PV air in the form of spiral bands. Vortex merger occurs when a vortex moves sufficiently close to a PV source. This process also produces inner spiral bands. The inner bands modeled in this study were found to project almost entirely onto the rotational modes, thus suggesting they are a slow-manifold phenomenon rather than a gravity wave phenomenon as previously proposed. Outer bands, which typically form at a radius greater than 500 km from the vortex center, are found to occur as a result of the intertropical convergence zone (TICZ) breakdown. Both types of bands are found to be stabilized by the adverse shear created by the main vortex. All theories are tested through the integration of a limited area, normal mode, spectral model. Dissert. Abstr.

OBSERVED ANNUAL AND INTERANNUAL VARIATIONS IN TROPOSPHERIC WATER VAPOR Ph.D. Thesis
Dian Judith Gaffen 1992 245 p
Avail: Univ. Microfilms Order No. DA9238477

Radiosonde observations from a global network of 56 radiosonde stations for 1973-1990 are used to describe and quantify annual and interannual variations of tropospheric water vapor. Taking care to identify data inhomogeneities related to changes in instruments or observing practices, monthly mean and anomaly data sets are constructed for dew point, specific humidity, relative humidity, temperature and precipitable water from the surface to 500 mb. Local annual cycles of tropospheric humidity can be classified according to the amplitude and phase of humidity variations which define five humidity regimes. For two regimes, both in middle and high latitudes, relative humidity is fairly constant while the annual cycle of precipitable water is in phase with that of temperature. At some midlatitude stations with a monsoon-like climate, seasonal relative humidity variations are large. In the tropics, seasonal relative humidity variations, especially above the boundary layer, dominate the annual cycle of precipitable water, and precipitable water variations are not related to temperature variations. Correlations of temperature and specific humidity anomalies are generally positive outside the tropics, suggesting that atmospheric warming is associated with increases in water vapor content. However, correlations of temperature and relative humidity anomalies are sometimes not significant and are often negative (e.g., in mid- and high latitude continental regions). Thus relative humidity is not always insensitive to temperature changes. In the tropics, tropospheric water vapor and temperature variations are not well correlated. An empirical orthogonal function analysis of tropical specific humidity variations identified two important modes of variability. The first is a step-like increase in specific humidity that occurred in about 1976-1977, and the second is associated with the El Nino phenomenon. The increase is consistent with the results of an extensive trend analysis of the data, which showed evidence for increases in precipitable water at about half of the 39 studied, decreases at three and no statistically significant trend at the others. Precipitable water trends were closely related to trends in dew point and specific humidity, as one would expect, but they were not always related to temperature trends. In addition, statistically significant relative humidity trends, both positive and negative, were found. Dissert. Abstr.

ON THE VERTICAL STRUCTURE OF SEASONAL, INTERANNUAL AND INTRASEASONAL FLOWS Ph.D. Thesis
Steven Reino Gilbert 1992 216 p
Avail: Univ. Microfilms Order No. DA9305145

The vertical structure of the height and wind fields associated with the seasonal, interannual, and intraseasonal cycles is documented by making use of global ECMWF operational analyses for seven pressure levels (1000-100 mb) and spanning a 10 year period (1980-89). The role of tropical convection is examined for each of these time scales. The seasonal cycle is described through the structure of the geopotential height field standing waves, the vertical structure of the first seven wavenumbers of the rotational and divergent winds, and latitude/time cross-sections for the vertical structure of the planetary waves. The change in the vertical structure from the internal mode combinations found in the tropics to a dominant external mode of the extratropics occurs rapidly and within 10 degrees of the convective source regions. Extensive use is made of a primitive equation (PE) model, as a diagnostic tool, to explore the extent to which tropical

heating might influence the extratropical vertical structure. The PE response indicates the possibility that 25-40 percent of the Northern Hemisphere and 30-55 percent of the Southern Hemisphere kinematic vertical structure could be the result of tropical heating. Two significant El Nino/Southern Oscillation (ENSO) events occur during this 10 year period and their vertical structures are examined. The cold phase is found to be dominated by higher internal modes than the warm phase. This may be linked to different air-sea interactive processes during cold and warm ENSO phases. The tie to tropical convection is also seen in the PE model response which shows wave trains and zonal wind maxima moving westward from the war to cold phase of the ENSO events, consistent with observations. The intraseasonal oscillation, as found in the near-equatorial 200 mb velocity potential, is composited for three seasons. A link between this oscillation and tropical convection is only clearly established during the convective phase, when convective activity is present across the Western Pacific and Indian Oceans. Composite cases for each season are selected to be in phase with one another and during times when the convective phase of the intraseasonal oscillation is strong. It is found that, when convective regions in the composites are collocated with those present in the seasonal average, the kinematic vertical structure is dominated by the two deepest vertical modes. This is different for other locations, where the convection in the composites does not coincide with regions of convection in the seasonal average. In this case the kinematic vertical structure favors higher internal modes.

AN ANALYSIS OF MESOSCALE CONVECTIVE SYSTEMS OBSERVED DURING THE 1992 TROPICAL CYCLONE MOTION FIELD EXPERIMENT M.S. Thesis

Eric J. McKinley Dec. 1992 113 p

(AD-A260889) Avail: CASI HC A06/MF A02

An analysis of two tropical Mesoscale Convective Systems (MCS) observed during the Tropical Cyclone Motion-92 (TCM-92) mini-field experiment is accomplished. A discussion of TCM-92, its primary and secondary missions, and the resulting data sets is provided. Primary data sets for the two cases include high-density (one minute) WC-130 aircraft data, 44 omega dropwindsondes, and visual and infrared (IR) geostationary satellite imagery. The observed characteristics exhibited by the tropical MCS's of the two cases are related to the hypothesized characteristics of midlatitude MCS's. Thus, the goal of the analyses is to document, for the first time, the horizontal and vertical scales in terms of the expected structure and evolution of the tropical MCS. The MCS's of the two cases were in the mature and decaying stages of the convective life cycle. Mid-level (500 mb) vortices that are apparently created in the stratiform rain regions of the MCS's are clearly discernable in the wind fields. In both cases, these vortices are seen to build upward to 300 mb or originate higher than the 500 mb surface. Downward translation of the vortex to 700 mb is evident in both aircraft and satellite data in one case. Convective signatures in the temperature and dewpoint fields are not as significant as the wind fields. Because signatures are observed in the synoptic scale, such as anticyclonic outflow in the MCS regions, these systems apparently were significant mesoscale features of sufficient intensity and duration to alter the large-scale regime for over 24 h. SETTING VALUES FOR TDWR/LLWAS 3 INTEGRATION PARAMETERS

Rodney E. Cole and Russell F. Todd 5 Feb. 1993 21 p

(Contracts DTFA01-89-Z-02033; F19628-90-C-0002)

(AD-A260740; DOT/FAA/NR-92/12) Avail: CASI HC A03/MF A01

In 1993 the FAA will begin deploying the Terminal Doppler Weather Radar (TDWR) at selected airports in the United States. Forty-five TDWRs will be collocated with LLWAS 3 systems, and the FAA has decided that all TDWRs collocated with LLWAS 3 systems must be integrated with LLWAS 3 prior to commissioning. The algorithm chosen to perform this integration must be supplied with a set of site-specific parameters. This report gives guidance on how to set the values of theme integration parameters. DTIC

LAND SURFACE PROCESSES AND CLIMATE MODELING Ph.D. Thesis

Lahouari Bounoua 1992 210 p

Avail: Univ. Microfilms Order No. DA9306028

A simple but realistic parameterization of ground wetness is developed and implemented in the FSUGSM to model in climate. Specifically, a soil moisture parameter based on a moisture budget, is introduced to estimate the Bowen ratio. It is expressed as an evolutive function of the model predicted rainfall, surface temperature and takes into account ground characteristics through its dependence on albedo and surface elevation. This scheme is used in conjunction with a prognostic equation for surface temperature to determine the surface fluxes. A global spectral model is used to perform two parallel forecasts, one of which includes the new scheme. Monthly situations for selected variables are presented. Comparison of the components of the surface energy balance are carried out for different types of climatic regime over Africa during summer. The new scheme captures the essence of the known physics in simple formulation of the processes and introduced interesting modulation of the fluxes. Reduction of the surface temperature and its diurnal cycle is observed. This is particularly evident over arid zones. An important and coherent interaction between the physical processes has resulted from the introduction of the scheme and led to better representation of the distribution of the heat sources at the surface. Realistic rainfall rates and distribution are obtained over the Sahelian region. Significant improvement has been introduced in the prediction of primary variables near the surface. The effect of the new land surface processes parameterization was, however, not clearly discernible in the upper level model atmosphere structure.

TROPICAL CYCLOGENESIS IN THE WESTERN NORTH PACIFIC Ph.D. Thesis

Raymond Milton Zehr 1992 231 p

Avail: Univ. Microfilms Order No. DA9303909

Tropical cyclogenesis in the western North Pacific is characterized by an early convective maximum which precedes the initial appearance of a tropical depression. The convection is quantified from cloud areas specified by cold infrared temperature thresholds with 3-hourly GMS satellite data. It is hypothesized that this convective maximum represents an important process associated with tropical cyclogenesis and is a response to large-scale (synoptic-scale) forcing. A conceptual model is described in which the early convective maximum is viewed as a necessary but not sufficient condition for tropical cyclone formation. An important change in the wind field takes place in response to the convective maximum. A weak mesoscale vortex is initiated and is located within the larger broad-scale cyclonic circulation of the pre-existing tropical disturbance. However, the first substantial decrease in central sea-level pressure and resultant increase in surface wind speed occur at a later stage of tropical cyclogenesis. Typically, the early convective maximum and associated mesoscale vortex formation precede first designation as a tropical storm by 2-3 days. The 850 mb and 200 mb objective analyses of conventional data are used to classify different synoptic-scale patterns associated with the formation of fifty individual tropical storms and typhoons during 1983-1984. Animated satellite imagery and aircraft reconnaissance data provide observations of deep convection and low-level winds for more detailed analysis. Twenty-four non-developing tropical disturbances which persisted for at least two days in the climatologically favorable genesis region are also investigated. Quantitative IR satellite analysis and 850 mb and 200 mb objective analyses of relative vorticity, divergence, and vertical wind shear allow comparisons among individual non-developing and developing disturbances. Small vertical wind shear, sufficient low-level convergence, and sufficient low-level relative vorticity are shown to be necessary conditions for tropical cyclogenesis. One or more of the three conditions can usually be identified as being deficient with individual cases of non-developing disturbances.

PRESSURE TORQUES AND CIRCULATION CHANGES IN ROCKY MOUNTAIN LEE CYCLONES Ph.D. Thesis

Alan C. Czarnetzki 1992 232 p

Avail: Univ. Microfilms Order No. DA9231196

The transfer of absolute dynamic circulation across the earth-atmosphere interface by pressure stresses in Rocky Mountain lee cyclones is examined through the use of Bjerknes' (1937) relation between stress and the tendency of absolute dynamic circulation. The pressure stress that leads to the horizontal acceleration of atmospheric circulation at the earth-atmosphere

interface results from the horizontal component of the hydrostatic weight of the atmosphere resting against the sloped terrain. The azimuthally-integrated pressure torque is the azimuthal integral of the tangential component of the pressure gradient force. It is equal to the azimuthal integral of the vertical derivative of the horizontal surfaces of the coordinate system being utilized and the contribution from the azimuthal pressure stress where the coordinate surfaces intersect the mountain. A positive (negative) vertically-integrated torque indicates a transfer of absolute dynamic circulation from (to) the earth. The tendencies of absolute dynamic circulation and the pressure torque are found to be the same order of magnitude. Negative pressure torque dominates the lower-tropospheric layers of all four simulations, indicating the transfer of absolute dynamic circulation from the atmosphere to the earth. The presence of higher pressure to the north of the lee cyclone and a pressure trough extending to the south of the cyclone are found to be crucial to explaining the sign and intensity of the pressure torque. The vertically-integrated west-to-east component of pressure drag per unit length across the Rocky Mountains is also computed. The results aid in the development of a conceptual model of the relation between the earth-atmosphere transfer of storm angular momentum on the cyclone scale and the angular momentum component along the earth's axis of rotation on the planetary scale. The pressure distributions which produces the negative mountain-induced pressure torque, and thus removes angular momentum from the cyclone, also returns eastward angular momentum to the earth by enhancing the pressure drag across the mountains to the south of the lee cyclone. This indicates that the transfer of the two components of absolute angular momentum between the atmosphere and earth are coupled. Dissert. Abstr.

POLARIZING MICHELSON INTERFEROMETER FOR MEASURING THERMOSPHERIC WINDS Ph.D. Thesis
John C. Bird 1991 219 p
(ISBN-0-315-70442-X) Avail: Univ. Microfilms Order No. DANN70442

The Polarizing Atmospheric Michelson Interferometer, PAMI, a new version of the Wide Angle Michelson Interferometer, is used to measure winds in the thermosphere. In the polarizing instrument, the optical path difference is changed simply by rotating a polarizing filter external to the interferometer. This allows a very simple scanning mechanism. PAMI's general behavior has been modeled in terms of Meuller matrices providing a framework for the analysis of partial polarization states within the Michelson Interferometer (MI). A field instrument based on the above concept was designed and built. PAMI is similar to other instruments such as WAMDII (Shepherd et al., 1985) that measure thermospheric winds and temperatures, retaining the benefits of high light throughput, while offering advantages including lower cost, simplicity, and portability. PAMI was constructed from readily available components wherever possible to facilitate replacement. The instrument is highly sensitive and thus is designed to be used for field measurements at locations far from city lights. Results are shown from the AIDA observation campaign in Puerto Rico (17 deg 57 min 0 sec N, 66 deg 52 min 42 sec W) where coordinated observations were made by PAMI along with other optical and radio measurements during April and May 1989. Intensities of the green line layer at 95 km were compared to those observed by several other instruments. For example, MORTI (Mesopause Oxygen Rotational Temperature Imager), a colocated instrument which was looking at the 94 km 867.6 nm molecular oxygen emission. MORTI and PAMI emission rates were found to show the same trends. PAMI intensities were also compared to two green-line photometers. In these comparisons the trends in observed emission rates were the same for all three instruments. On the brightest night recorded during April, the zenith emission rate reached over 400 Rayleighs; emission enhancements were sometimes related to auroral events. During the observing period of April 4 to April 11, 1989, most of the observations of the 95 km airglow were after midnight where the winds were found to be generally towards the north east at about 50 to 100 m/s. During auroral activity this wind vector always turned counterclockwise, towards the west. During the nights of May 2 and May 6 these wind vectors follow a wave-like variation in magnitude and direction. It is concluded that auroral activity changes the global circulation in a way that sometimes transports increased amounts of oxygen atoms over Arecibo. Wind comparisons were made with a Fabry-Perot interferometer operating at the same time at the Arecibo observatory, 60 km away. The agreement was generally good, with some differences in detail, in some cases, for the eastward wind component. Dissert. Abstr.

TROPICAL CYCLONE/UPPER-ATMOSPHERIC INTERACTION AS INFERRED FROM SATELLITE TOTAL OZONE OBSERVATIONS Ph.D. Thesis
Edward Burton Rodgers 1992 291 p
Avail: Univ. Microfilms Order No. DA9303893

The Nimbus-7 Total Ozone Mapping Spectrometer (TOMS) was used to map the distribution of total ozone within and surrounding western North Atlantic and North Pacific tropical cyclones that occurred from 1979-1982. It was found from numerical model simulations and diagnostics and satellite observations that the distribution of total ozone within the subtropical upper-tropospheric waves during the tropical cyclone season correspond well with the variation of thermodynamic parameters (i.e., temperature, thickness, geopotential heights) near the tropopause and the regions of strong stratospheric and tropospheric exchange processes. These results are similar to previous middle latitudinal observations. It was also found that the three-dimensional transport processes associated with both the western North Atlantic and Pacific tropical cyclone's outflow jet induced secondary circulation and the strong vertical motions associated with active deep convective and eye regions helped to modify the total ozone distribution that is usually observed within these subtropical upper-tropospheric waves. The tropical cyclone induced modifications of the total ozone in the upper-tropospheric waves became greater as the tropical cyclone became more intense and the three-dimensional transpost processes associated with the outflow jet, convection and eye strengthened. The strong relationship between total ozone distribution and the variation of the tropopause topography, made it possible to use TOMS to monitor the propagation of the subtropical upper-tropospheric waves and the mutual adjustment between tropical cyclones and their upper-tropospheric and lower-stratospheric environment when these tropical cyclones and the upper-tropospheric waves interacted. These total ozone patterns during tropical cyclone and upper-tropospheric wave interaction reflected the three-dimensional upper-tropospheric transport processes that were conducive for storm intensification, weakening, or recurvature. The total ozone distribution indicated that high latitude western North Atlantic and North Pacific tropical cyclones that intensify (do not intensify) are (1) within 10 degrees (15 degrees) latitude of weak (strong) upper-tropospheric troughs that are moderately rich (very rich) in total ozone; (2) have outflow channels that extend (do not extend) large distances from their centers; and (3) have (do not have) subsiding ozone rich stratospheric air southwest of their centers. The total ozone distribution indicated that low latitude North Pacific tropical cyclones that intensify (do not intensify) com (do not come) into close proximity with weak upper-troposphere troughs that are moderately rich in ozone and have outflow channels that do (do not) extend large distances from the centers. Finally, the total ozone distribution indicated that western North Pacific tropical cyclones that turn left (right) are within approximately 15 degrees latitude downstream of an ozone-poor (ozone-rich) upper-tropospheric ridge (trough). VECTOR RADIATIVE TRANSFER MODEL: APPLICATION TO RAINFALL RETRIEVAL WITH MICROWAVE RADIOMETRIC DATA Ph.D. Thesis
Fuzhong Weng 1992 202 p
Avail: Univ. Microfilms Order No. DA9303904

A new vector radiative transfer model is developed. The physical processes included are thermal emission, scattering, absorption, and bidirectional reflection and emission at the lower boundary. The medium may be forced at the top boundary by polarized parallel or diffuse radiation and by polarized internal and boundary thermal sources as well. The model is unconditionally stable for an arbitrarily large number of streams and arbitrarily large optical depths. Brightness temperature structures of mesoscale precipitation systems (MPS's) from radiative transfer modeling are presented and analyzed. The analysis reveals several results. Polarization brightness temperatures at 85.50 GHz well reflect structures of convective and stratiform precipitation in the MPS's. Distinct contrasts between PCT's at 85.50 GHz in the convective and stratiform regions in the MPS's exist. Horizontally polarized brightness temperatures at 19.35 and 37.00 GHz are more sensitive to the light rain over ocean than those at other frequencies and polarization states. The PCT's at 37.00 and 85.50 GHz well correlate

the precipitation ice water path in the MPS's and the PCT at 19.35 GHz correlates the precipitation liquid water path. Inversion relations between PCT's and rain rates are derived from radiative transfer calculations in terms of a new precipitation model. This model includes precipitation-sized ice hydrometeors, raindrops, and cloud-sized hydrometeors. Error sensitivity study shows that variations of cloud water content are major causes responsible for errors of retrieved rain rates and that light rain rates retrieved from low frequency inversion relations include larger uncertainty than those from high frequency inversion relations. A microwave multi-channel algorithm is developed for retrieving monthly precipitation over global land and ocean. The probability density function of rain rates is employed in the algorithm. Retrieved monthly precipitation exhibits consistency with presently existing precipitation data in terms of large scale features and discrepancy in terms of detailed structures. Dissert. Abstr.

THE NORTH DAKOTA THUNDERSTORM PROJECT Final Report, Apr. 1989 - Mar. 1991
20 Nov. 1991 61 p
(Grant NA89RA-H-09088)
(PB93-153039) Avail: CASI HC A04/MF A01

The North Dakota Thunderstorm Project (NDTP) was a national scale research program conducted in central North Dakota during June and July, 1989. The program was hosted and coordinated by the North Dakota Atmospheric Resource Board and funded jointly by the National Oceanic and Atmospheric Administration (NOAA), the State of North Dakota, and the National Science Foundation. Data collection with four Doppler radars, six aircraft, and a variety of supporting instrumentation began 12 June 1989, and continued through 22 July 1989. In all, 106 of the nineteen various predefined experiments were conducted, though severe storms were fewer in number than expected. Several different atmospheric tracer techniques were employed including gaseous (sulfur hexafluoride), radar chaff, natural (ozone, carbon monoxide), and fluorescent beads. Author (DTIC)

Currently in numerical weather prediction, two avenues for cloud forecasting are being pursued by the research community. The conventional one defines cloud coverage as a function of prevailing relative humidity. The new method explicitly predicts clouds as a variable of the model. Our research effort covers both avenues. The major results of our research are: (1) The threshold relative humidity approach exhibits a decay of cloud fractions during the medium range weather forecasts. The major errors in the prediction appear to occur in the first 24 hours, an initialization problem. Observed clouds appear to exhibit more of a resilience than is demonstrated by the models. Long lasting cloud debris (i.e., nonprecipitating elements) are not reasonably handled by the model. This deficiency is related to the strong selection rules imposed by the model for the existence of clouds; (2) The explicit treatment of clouds where the cloud water mixing ratio is used as a dependent variable of the model, appears to handle long lasting clouds in a more realistic manner. It does not show the rapid spin-down feature present in the threshold relative humidity approach; and (3) A large effort on physical initialization is currently underway in our global modeling effort. This provides a consistent analysis of the humidity variable with respect to the rain rates (as seen from satellite based measurements). DTIC

RAINFALL FREQUENCY ATLAS OF THE MIDWEST
Floyd A. Huff and James R. Angel 1992 151 p Sponsored by Climate Analysis Center and National Environmental Satellite Service
(PB93-164606; ISWS/BUL-71; MCC-RR-92-03) Avail: CASI HC A08/MF A02

The report presents the results and methodology of an intense study of rainfall frequency relationships throughout the Midwest (Illinois, Indiana, Iowa, Kentucky, Michigan, Minnesota, Missouri, Ohio, and Wisconsin). Using the 275 long-term daily reporting stations from the National Weather Service (NWS) cooperative network, supplemented by 134 daily reporting stations with shorter records, rainfall amounts have been determined for recurrence intervals from 2 months to 100 years and for durations of 5 minutes to 10 days. The results are presented as maps and as climate division averages

in tabular form. Several special rainage networks were used to develop relationships between amounts for 24 hours and less. The report also examines the time distributions of heavy rainfall over time and other storm characteristics such as storm orientation and movement. The assumption of spatially independent observations between stations is also discussed.

NATURAL AND AUGMENTED SNOWFALL GROWTH PROCESSES AND THEIR INTERACTIONS WITH THE NATURAL AND MODIFIED AEROSOL Final Report, 1 Mar. 1989 - 30 Apr. 1990
J. Warburton Jul. 1991 57 p
(Grant NA89RA-H-09087)
(PB93-153096) Avail: CASI HC A04/MF A01

The second annual report describes the activities performed under seven separate tasks. These tasks dealt with the development of a trace chemical method of assessing the effects of seeding in a snow producing environment and the use of the stable isotopes of water for assessing the regions of ice-phase water capture in the cloud systems from which precipitation fell in the study regions. They also dealt with the theoretical aspects of these trace chemical programs of study and with the roles which trace impurities can play in affecting the growth characteristics of ice particles in supercooled clouds and of the shapes and number fluxes of ice crystals which occur under both natural and artificially seeded conditions. These tasks also included studies of the supercooled liquid water and ice contents of winter storms over the central Sierra Nevada, both spatially and temporally through the use of ground-based remote sensing radar and microwave radiometers. Some work was also conducted on the further development of new aircraft instrumentation for measuring atmospheric motions and the microphysical composition of winter orographic clouds.

(AD-A260673) Avail: CASI HC A03/MF A01

A recent review paper, to appear in the journal Advances in Atmospheric Sciences, summarizes the work completed under this grant. A copy of this review is enclosed as an appendix to the report. The approach we have followed is to first make a very high resolution model forecast of a recurving typhoon. Given a good forecast on the medium range with a comprehensive physical-dynamical model we next proceeded to evaluate residue-free budgets of vorticity and divergence following the model's output history. The residue-free budgets follow the model equations and thus carry a lot of useful information on the recurvature dynamics. Specifically, we have evaluated the residue-free budgets of vorticity and divergence for a 6 day period.

This report describes, in detail, the SBIR Phase 2 contracting effort provided for by NASA Contract Number NAS8-38481 in which a prototype Rain Rate Sensor was developed. FWG Model RP101A is a fully functional rain rate and droplet size analyzing instrument. The RP101A is a fully functional rain rate and droplet size analyzing instrument. The RP101A consists of a fiber optic probe containing a 32-fiber array connected to an electronic signal processor. When interfaced to an IBM compatible personal computer and configured with appropriate software, the RP101A is capable of measuring rain rates and particles ranging in size from around 300 microns up to 6 to 7 millimeters. FWG Associates, Inc. intends to develop a production model from the prototype and continue the effort under NASA's SBIR Phase 3 program.

A CLIMATOLOGY OF POLAR LOW OCCURRENCES IN THE NORDIC SEAS AND AN EXAMINATION OF KATABATIC WINDS AS A TRIGGERING MECHANISM M.S. Thesis
Kenneth A. Wos Dec. 1992 154 p
(AD-A261719) Avail: CASI HC A08/MF A02

This study examines polar low formation frequency, origin region and storm tracks in the entire Nordic Sea region for a complete polar low season and identifies the prevailing synoptic situation common to polar low formation. The number of polar lows detected through TIROS-N satellite imagery between September 1988 and May 1989 was significantly greater than one would expect from previous studies. Many polar lows were detected over the land areas of Greenland, Iceland and Svalbard away from a direct surface heat source. The storms detected over Greenland generally formed at the outflows of glacial valleys. To determine probable formation areas, polar lows were linearly backtracked along the reciprocal of their storm tracks. A significant number were backtracked to glacier outflows. These formation locations suggest a katabatic influence on storm formation, possibly due to vortex stretching, or the enhancement and distortion of an over-ice or over-land boundary layer baroclinic zone. Katabatic flows were examined by analyzing one month of regional surface synoptic observations and NOGAP 1000 mb height gradients. To develop aids to enhance polar low forecasting, monthly mean 1000 and 500 mb fields for chart times closest to polar low detection, or time backtracked to Northern, Central and Southern Greenland, were calculated from archived NOGAPS 12 hourly analyses and compared to the monthly averaged climatology fields of height and temperature.

EFFECTS OF TAIWAN OROGRAPHY ON THE MOTION AND STRUCTURE OF TYPHOONS M.S. Thesis
Tien C. Yeh Dec. 1992 308 p
(AD-A261819) Avail: CASI HC A14/MF A03

Effects of steep island terrain on typhoon motion and structure changes are studied by both observational analyses and numerical simulations. The analyses involve calculation of center position deviations from a second-order polynomial curve fitted to the best tracks, and an empirical orthogonal function analysis to determine the terrain-induced surface structures. The simulations use a limited-area model, with a elliptical-shaped barrier and a 'spun-up vortex' to represent the typhoon, to demonstrate the sensitivity on track and structure relative to vortex intensity, approach direction and translation speed. Both observational and simulation studies show that the orography induces significant track deflections and structure distortions, especially for a weaker and slowly moving typhoon approaching central or southern Taiwan. As the typhoon approaches, the outer edge of the circulation accentuates the blocking effect of the barrier. Asymmetric gyres are induced by a vortex-terrain interaction as the vortex moves closer to the barrier, which accounts for the significant track deflections from a simple barrier effect. The simulations suggest that a center-following algorithm based on the wind field would be more representative than on the pressure field. A track discontinuity occurs when the secondary vortex created from flow deflections around the barrier becomes the primary center downstream.

AN INVESTIGATION INTO THE CAUSATIVE MECHANISMS FOR EXPLOSIVE CYCLONE DEVELOPMENT OVER THE ATLANTIC Final Report, 1991 - 1992
Susan S. Minton 8 May 1992 72 p
(AD-A261831; USNA-TSPR-191) Avail: CASI HC A04/MF A01

Explosive cyclogenesis is defined as the rapid intensification of a marine cyclone at the rate of 24 mb in a 24 hour period (Sanders, 1980). Such cyclones produce very intense storms which result in gale-force winds, heavy precipitation, and severe sea states along the East Coast of the United States. Green (1988) suggested that an atmospheric inversion (or lid) may play an important role in the explosive development of marine cyclones. The atmospheric lid condition is present prior to and upwind of cyclone development. This study examines three ERICA, the Experiment on Rapidly Intensifying Cyclones over the Atlantic, cases for the presence of the atmospheric lid condition. Results show that the lid condition was present 12-48 hours prior to explosive cyclone development in ERICA cases IOP 4 and 5, while the lid condition was not present in the control

case, LOP 6P. Moreover, the prediction of explosive marine cyclones would be improved with the use of operational numerical weather prediction models, such as the Nested Grid Model, provided these models have adequate vertical resolution. DTIC

AN OBSERVATIONAL STUDY OF THE LOCAL AND REMOTE RESPONSE OF THE EQUATORIAL PACIFIC TO WESTERLY WIND EVENTS DURING THE 1991-92 EL NINO M.S. Thesis
Grant A. Cooper, IV Dec. 1992 109 p
(AD-A261777) Avail: CASI HC A06/MF A02

The upper equatorial Pacific ocean response to anomalous westerly wind forcing during the 1991-92 El Nino was examined using observed oceanographic and atmospheric data from equatorial moorings and the Navy's operational atmospheric analyses. A strong 30-60 day signal was observed in the zonal winds and is mainly a result of westerly wind events. The local response to anomalous westerly winds differed between the western and eastern equatorial Pacific. In the western Pacific, westerly wind events tended to produce rapid decreases in sea surface temperature (SST) (up to 1 deg C). These decreases were followed several days later by SST increases due to horizontal warm water advection and downwelling. In the central and eastern equatorial Pacific, westerly wind events were expressed mainly as weakenings of the easterlies. These weakenings caused decreases in equatorial upwelling and SST increases. Westerly wind events in the western Pacific were also associated with large thermocline temperature fluctuations (on the order of 10 deg C) in the central and eastern equatorial Pacific. These fluctuations propagated eastward at phase speeds consistent with first baroclinic equatorial Kelvin wave dynamics (i.e., 2.0 - 3.5 m/s). The ocean temperature fluctuations indicate basin wide wavelengths (about 15 x 103 km), with periods of 30-60 days. DTIC

DEVELOPMENT AND TESTING OF IMPROVED TECHNIQUES FOR MODELING THE HYDROLOGIC CYCLE IN A MESOSCALE WEATHER PREDICTION SYSTEM Annual Technical Report, 15 Dec. 1991 - 14 Dec. 1992
Thomas Warner, Toby N. Carlson, and J. M. Fritsch Jan. 1993 11 p
(Contract F49620-92-J-0118)
(AD-A261454; AFOSR-93-0045TR) Avail: CASI HC A03/MF A01

Soil-water content is the single most important land-surface variable in atmospheric prediction models. Sophisticated surface physics-soil hydrology parameterization schemes are beginning to be used in mesoscale weather prediction models; however, soil-water content is not measured over large enough areas on a regular basis where it could provide suitable initial conditions for those models. Therefore, the initialization of the soil-water content profile has to depend on a knowledge of the hydrological balance of the soil in the area represented by each mesoscale-model grid point. In turn, this information must be obtained from a knowledge of the precipitation, evaporation, and substrate recharge from the water table. We have undertaken the task to develop a systematic means for providing initial values of the soil-water-content profile for the Penn State/NCAR Mesoscale Model. This task is composed of three phases. The first phase is to develop an off-line, one-dimensional hydrological model that is driven by conventional meteorological, soil, and vegetation data. The second phase is to develop the database to drive the hydrological model in a form that is compatible with the surface physics-soil hydrology parameterization scheme utilized in the mesoscale model (i.e., the Biosphere-Atmosphere Transfer Scheme (BATS)). The last phase consists of generating an automated update of the soil-water content profile at each of the mesoscale-model grid points. DTIC

THE INITIATION OF LIGHTNING AND THE GROWTH OF ELECTRIC FIELDS IN THUNDERSTORMS Annual Report, 10 Jul. 1991 - 9 Jul. 1992
John Latham Dec. 1992 90 p
(Contract F49620-92-J-0020)
(AD-A261455; AFOSR-93-0046TR) Avail: CASI HC A05/MF A01

As specified in the original proposal, there exits mounting evidence that the growth of strong electric fields--culminating in lightning--in the great majority of thunderstorms is intimately linked with--and probably contingent upon--the concomitant development of the ice-phase. Thus, significant progress in the elucidation of electrification mechanisms requires an improved understanding of the complex set of processes involved in cloud glaciation. Accordingly, primary emphasis has been devoted in this first year of a proposed 3-year study, to the analysis and interpretation of data emanating from major airborne experiments in which a primary objective was to seek a superior understanding of the initiation and development in cumulus clouds of the type which often become strongly electrified. THE EFFECTS OF CLOUD INHOMOGENEITIES UPON RADIATIVE FLUXES, AND THE SUPPLY OF A CLOUD TRUTH VALIDATION DATASET Semiannual Progress Report, 1 Jul. - 31 Dec. 1992
Ronald M. Welch 1993 103 p
(Contract NAS5-31718)
(NASA-CR-191711; NAS 1.26:191711; SA-2) Avail: CASI HC A06/MF A02

A series of cloud and sea ice retrieval algorithms are being developed in support of the Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) Science Team objectives. These retrievals include the following: cloud fractional area, cloud optical thickness, cloud phase (water or ice), cloud particle effective radius, cloud top heights, cloud base height, cloud top temperature, cloud emissivity, cloud 3-D structure, cloud field scales of organization, sea ice fractional area, sea ice temperature, sea ice albedo, and sea surface temperature. Due to the problems of accurately retrieving cloud properties over bright surfaces, an advanced cloud classification method was developed which is based upon spectral and textural features and artificial intelligence classifiers. BOUNDARY LAYER COUPLING BETWEEN AN EXPLOSIVE CYCLONE AND THE GULF STREAM DURING ERICA Final Report, 1 Oct. 1990 - 30 Sep. 1991
Warren B. White and Dave Rogers 1 Mar. 1993 17 p
(Contract N00014-90-J-1716)
(AD-A261577) Avail: CASI HC A03/MF A01

Oceanographic and atmospheric observations collected during the Experiment on Rapidly Intensifying Cyclones over the Atlantic (ERICA) were analyzed for an explosive cyclone event occurring in 13-14 Dec. 1989, labeled IOP-2. This explosive cyclone formed over the Gulf Stream Front adjacent to Cape Hatteras; it developed independently of upper air baroclinicity and subsequently tracked the Gulf Stream to the east from 74 deg W to 60 deg W over the following two-day period. A kind of boundary layer coupling that existed between the Gulf Stream and the explosive cyclone, with the Gulf Stream Front shown able to alter the boundary layer characteristics of the explosive cyclone and the explosive cyclone, in turn, shown able to alter the frontal character of the Gulf Stream was shown to exist. The effect of this boundary layer coupling, which amounted to a positive feedback between ocean and atmosphere, was to increase the gradient structure of the Gulf Stream by 10-20 percent from 73 deg - 60 deg W over just a few days. The effect of the boundary layer coupling upon the explosive cyclone is unknown. The atmospheric model employed was that of the planetary boundary layer. DTIC

(PB93-148435; NOAA-TM-NWS-SR-147) Avail: CASI HC A10/MF A03

The report is concerned with the tornado from an engineering point of view. The engineering perspective of tornado-induced damage should aid the meteorologist in his assessments of the tornadic windfield while, at the same time, draw the attention of the engineer who is concerned with developing wind resistant designs. A basic discussion of building failure mechanisms in windstorms is presented, since an understanding of failure phenomena is important to the treatment of subsequent topics. Following the development of background information on failure modes are treatments of tornadic windspeeds and near-ground windfields. These perspectives may be of value to both the meteorologist and the engineer. A major section on housing points out the usefulness, and limitations, of housing damage as an indicator of windspeed and windfield geometry. Further, the evaluation identifies deficiencies in design which should draw the attention of builders, architects, and engineers. Final topics include the role of atmospheric pressure change in inducing damage, tornado generated missiles, and discussions of unusual events. NTIS

OBSERVATIONS OF AN INTRATHERMOCLINE VORTEX Ph.D. Thesis
Lucy Marguerite OKeefe 1992 156 p
Avail: Univ. Microfilms Order No. DA9302556

This study describes the temperature and velocity structure of an intrathermocline vortex. We first estimate and discuss the vortex's propagation velocity. On this basis, we employ the 'frozen field' hypothesis to map time series into spatial sampling of the vortex. This yields an estimate of vortex structure. The chief priority of this study is to present this overview of the structure of an intrathermocline vortex. We add to the current state of knowledge by employing data which (unlike the hydrographic data which is generally employed in studies of these objects) is finely sampled in the horizontal dimension, at five depths from 300 meters below sea surface down to 5 meters above sea surface. The focus of further analysis of these observations is on delineation of interactions between the vortex and its background. The study will present observations which appear to characterize interactions between the vortex and its Gulf Stream background, and also between the vortex and the deep ocean flow.

ON THE GENERATION AND DISPERSION OF YANAI WAVES WITH A SPECTRAL CHEBYSHEV-COLLOCATION REDUCED-GRAVITY OCEAN MODEL Ph.D. Thesis
Brian Gerard Joseph Kelly 1992 129 p
Avail. Univ. Microfilms Order No. DA9306235

A spectral Chebyshev-collocation method is devised for the 1-1/2 layer non-linear reduced-gravity equations. Following a general description of spectral methods with their application to meteorological and oceanographic problems the implementation of the numerical technique is described. A bicharacteristic scheme is applied to solve the equations at the boundaries incorporating the boundary conditions. This treatment enables stable time integrations (spectral methods in general are very sensitive to boundary errors). A simple transfinite grid generation method is used to construct grids over irregular (non-rectangular) simply-connected domains. The model is used in a study of the dynamics of Yanai (or mixed Rossby-gravity) wave packets. These are of interest because of the observations of equatorial instability waves (which have the characteristics of Yanai waves) and their role in the momentum and heat budgets in the tropics. A series of experiments is performed to investigate the generation of the waves by simple cross-equatorial wind stress forcings in various configurations and the influence of a western boundary on them. They may be generated in the interior ocean as well as from a western boundary. The observations from all the oceans indicate that the waves have a preferential period and wavelength of around 26 days and 1000 km respectively. This is seen in the model results too and a plausible explanation is provided as being due to the dispersive properties of Yanai waves.

DYNAMICS OF GULF STREAM MEANDERS AND FRONTAL EDDIES IN THE SOUTH ATLANTIC BIGHT Ph.D. Thesis
Jerry L. Miller 1992 139 p
Avail: Univ. Microfilms Order No. DA9301242

As the Gulf Stream flows along the outer edge of the southeastern United States' continental shelf, it meanders on and offshore creating frontal eddies which influence the exchange of water between the shelf and the adjacent Atlantic Ocean on weekly time scales. The dynamics controlling the development of such features in this region, the 'South Atlantic Bight' (SAB) were investigated. Analyses of the low-frequency low-wavenumber behavior of the Gulf Stream front revealed two modes of meandering which have maximum amplitudes in the vicinity of the Charleston Bump and periods of a few months to a year. In the southern one-third of the SAB, these modes have small amplitudes and the frontal fluctuations are predominantly due to the meander/frontal eddy processes. The Princeton Ocean Model was tuned for conditions which prevail in the southern SAB and idealized numerical simulations of Gulf Stream meanders and associated frontal eddies were performed. The system was found to be sensitive to

both the amplitude and period of a small perturbation applied at the southern boundary and a case which produced events most similar to those observed in nature was studied in detail. The energetics indicate that the development of these features is controlled by a mixture of both baroclinic and barotropic instabilities of the mean Gulf Stream flow. The corresponding momentum balances are equally complex. While the along-isobath flow is predominantly in geostrophic balance, several of the nonlinear advection terms in both horizontal momentum equations play important roles in the space-time development of the flow. In particular, the vertical advection of horizontal momentum as well as frictional dissipation are now recognized as important contributions to the dynamical balances in the vicinity of the steep continental slope. NUMERICAL SIMULATION OF THE SEASONAL AND INTERANNUAL VARIABILITY OF THE TROPICAL ATLANTIC OCEAN CIRCULATION DURING THE 1980'S Ph.D. Thesis
Bohua Huang 1992 229 p
Avail: Univ. Microfilms Order No. DA9304336

A nine-year (1980-88) surface wind stress data set over the tropical Atlantic ocean is constructed based on the European Center for Medium Range Weather Forecasts (ECMWF) twice-daily wind analysis. Its quality is checked against an independent data set based on ship observations. A comprehensive analysis of these two data sets shows a strong seasonal cycle of the wind stress over the equatorial Atlantic ocean. Interannually, the stress field is dominated by a seesaw between the northeast and southeast trade winds, with anomalously strong (weak) southeast (northeast) trade winds during 1980-83 and a reversed pattern during 1984-88. Two nine-year simulations of the tropical Atlantic ocean circulation are performed with a general circulation model, one forced by the twice-daily, and second by monthly averaged ECMWF surface wind stresses. Comparisons with available observations show that the seasonal ocean circulation and interannual signals of the sea surface temperature (SST), i.e., the dipole oscillation and abnormal warmings, are reproduced qualitatively by both simulations. Further analysis shows that the seasonal cycle of the subtropical and tropical Atlantic wind stress and the interannual SST dipole oscillation is generally in balance with the seesaw pattern of the trade wind systems although wave processes are important during the transition of phase. In 1984, the transition of the SST dipole from north-warm/south-cold to its opposite occurred during an equatorial warming event. This warming event was initiated by the relaxation of equatorial easterly wind, which stimulated heat transfer first eastward along the equator, then to the southern ocean and caused a deepening of the thermocline in the Gulf of Guinea and the southern ocean. Another warming event occurred in 1987-88 which restored the disappearing north-cold/south-warm dipole. A comparison of the two simulations shows the effects of high frequency wind forcing on the oceanic circulation. In midlatitudes, high frequency wind fluctuations cool the upper ocean through increasing the transport of the sensible and evaporative heat to the atmosphere. Near the equator, high frequency wind fluctuations enhance vertical mixing in the upper ocean, increasing temperature near the thermocline. The high frequency wind also generates oceanic waves near the equator. However, these waves only have a small effect on the seasonal and interannual variability of the ocean circulation.

SIMULATION AND PREDICTION OF TROPICAL SST WITH A COUPLED OCEAN-ATMOSPHERE MODEL Ph.D. Thesis
Timothy N. Stockdale 1992 256 p
Avail: Univ. Microfilms Order No. BRD-98048

An ocean general circulation model (OGCM) is adapted to represent the tropical Pacific ocean. The model is tuned and tested by attempting to simulate the climatological seasonal cycle of the equatorial Pacific Ocean, with particular regard to the quantitative reproduction of the observed sea surface temperatures (SST's) and heat fluxes. Several errors in the model simulation are noted, the most serious being a cold bias in the central equatorial ocean. Possible causes of this cold bias (known to afflict many OGCM's) are investigated, and it is concluded that errors in the model representation of the Equatorial Undercurrent are partly responsible, while errors in the vertical mixing of heat may also be important. Two versions of a single baroclinic mode, equilibrium atmosphere model are developed. One of these is a usual Gill type model, and the other uses the same formalism to represent a boundary layer model of the atmosphere. The boundary layer atmosphere model enables explicit calculation of all the parameters for the Gill equations, and successfully reproduces observed stress anomalies. A coupled model is constructed from the OGCM, an atmosphere model, and a parameterization of heat flux. The atmosphere and heat flux models run in anomaly mode (i.e., they are driven by SST anomalies only), while the OGCM simulates the full state of the ocean. Coupled interactions in the model produce a slow eastward motion of the west Pacific warm pool, and this motion is sensitive to various model parameters. Although the model is able to give rise to some interesting types of long term behavior, realistic interannual variability similar to the observed El Nino and the Southern Oscillation is not produced. The coupled model is configured for forecasting future changes in SST, and a number of preliminary experiments made. Although the OGCM alone gives some indication of future large scale SST changes, the coupled model is not successful. The potential for short range prediction of detailed SST patterns is considered.

CRUSTAL DEFORMATION STUDIES IN SUBAERIAL PARTS OF THE WORLD OCEANIC RIFT SYSTEM: ICELAND AND AFAR Ph.D. Thesis
Freysteinn Sigmundson 1992 119 p
Avail: Univ. Microfilms Order No. DA9304603

Crustal deformation in Iceland and Afar, both subaerial parts of the oceanic rift system, is studied for a better understanding of tectonic processes and rheology in these areas. This thesis evaluates the mechanics of the 1991 Hekla eruption in Iceland, rheology and glacio-isostatic crustal movements around the Vatnajoekull ice cap in Iceland, and strain accommodation between overlapping spreading centers in Afar. Between January 17 and March 11, 1991, 0.15 cu km of lava erupted initially from several radial fissures and subsequently from a single fissure on the SE flank of the Hekla volcano in Iceland. Hekla is within an array of geodetic control points that were measured in 1989 using the Global Positioning System and re-measured during and after the eruption. Measurements of the lake level of Lake Langisjor at the SW edge of the Vatnajoekull ice cap in Iceland indicate a tilt of 0.26 plus or minus 0.06 microrad/year away from the ice cap between 1959-1991. The tilt is too large to be explained as an elastic response to the earth to ice retreat during this century or caused by change in the gravitational pull of the ice cap. Rather, it can be explained by sub-lithospheric viscous adjustment when the sub-lithospheric viscosity is 1 x 10(exp 18) - 5 x 10(exp 19) Pa s. Regional subsidence in historical times in SE Iceland can similarly be attributed to viscous adjustment resulting from the increased load of Vatnajoekull during the Little Ice Age. A GPS geodetic network was installed in the area to monitor further elevation changes. In August 1989 a sequence of m(sub b) 5-6 normal faulting earthquakes occurred in the area between the Ghoubbet Asal-Manda Inakir and Manda Haroro-Abhe Bad rifts in central Afar. Relocation of the events suggest they occurred on major faults in the Dobi graben located midway between the principal rift zones. The earthquakes are evidence that extensional strain is still occurring in the area. A previously proposed 'bookshelf' tectonic model for central and southern Afar has been modified to account for ongoing extension in the area between the principal rifts as well as distributed shear.

ERRORS CAUSED BY INCOMPATIBLE WIND AND BUOYANCY FORCING IN THE OCEAN GENERAL CIRCULATION MODELS M.S. Thesis
Yu-Heng Kuo Dec. 1992 73 p
(AD-A260894) Avail: CASI HC A04/MF A01

The Geophysical Fluid Dynamics Laboratory Modular Ocean Model (GFDL-MOM) is used to investigate the model difference between compatible and incompatible surface wind and buoyancy forcing. The atmosphere is a physical system in which surface wind and temperature fields are related, however in most ocean numerical models, the wind stress and buoyancy forcing are usually specified separately, i.e., no constraint between the surface wind stress and surface air temperature is considered. In reality, only one of these two fields can be prescribed in the atmosphere-driven ocean models. When the surface wind field is prescribed, the surface air temperature should be derived, and vice versa. If the two related fields are treated as totally independent in forcing the ocean models the results

will be distorted. Since the model solutions depend upon the atmospheric forcing, it is important that we study the compatibility between the wind and buoyancy forcings and the effect which incompatibility might have on the ocean numerical models. This study shows that the surface wind and buoyancy forcing widely used in ocean numerical models are incompatible. Such an incompatibility results in 21 percent error in the total northward transport of heat, 16 percent error in the total northward transport of salt, 25 percent error in v velocity, and 16 percent error in w velocity. (NASA-CR-193100; NAS 1.26:193100; RSL-TR-8241-1; RSL-TR-8243-1; AD-A261843) Avail: CASI HC A04/MF A01

Radar backscatter measurements from sea ice during the fall freeze-up were performed by the United States Coast Guard Icebreaker Polar Star as a part of the International Arctic Ocean Expedition (IAOE'91) from Aug. to Sep. 1991. The U.S. portion of the experiment took place on board the Polar Star and was referred to as TRAPOLEX '91 (Transpolar expedition) by some investigators. Before prematurely aborting its mission because of mechanical failure of her port shaft, the Polar Star reached 84 deg 57 min N latitude at 35 deg E longitude. The ship was in the ice (greater than 50 percent coverage) from 14 Aug. until 3 Sep. and was operational for all but 6 days due to two instances of mechanical problems with the port shaft. The second was fatal to the ship's participation in the expedition. During the expedition, radar backscatter was measured at C-band under a variety of conditions. These included measurements from young ice types as well as from multiyear and first-/second-year sea ice during the fall freeze-up. The sea ice types were determined by measurement of the ice properties at several of the stations and by visual inspection on others. Radar backscatter measurements were performed over a large portion of the ship's transit into the Arctic ice pack. These were accompanied by in situ sea ice property characterization by the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) at several stations and, when snow was present, its properties were documented by The Microwave Group, Ottawa River (MWG). ADCIRC: AN ADVANCED THREE-DIMENSIONAL CIRCULATION MODEL FOR SHELVES, COASTS, AND ESTUARIES. REPORT 1: THEORY AND METHODOLOGY OF ADCIRC-2DDI AND ADCIRC-3DL

R. A. Luettich, Jr., J. J. Westerink, and Norman W. Scheffner Nov. 1992 143 p

(AD-A261608; CERC-TR-DRP-92-6) Avail: CASI HC A07/MF A02

This report describes the theory, methodology, and verification of the ADCIRC (ADvanced CIRCulation) finite element numerical models. The ADCIRC-2DDI model is a two-dimensional, depth-integrated hydrodynamic model. The ADCIRC-3DL model is a three-dimensional model that couples the external mode solution generated by ADCIRC-2DDI to a locally one-dimensional internal mode solution. The numerical internal mode solution can be obtained using either velocity or stress as the dependent variable. The ADCIRC model was developed to simulate hydrodynamic circulation along shelves, coasts, and within estuaries. To allow long numerical simulations (on the order of a year) over very large computational domains (for example, the entire east coast of the United States), ADCIRC was designed to have high computational efficiency and has been tested extensively for both hydrodynamic accuracy and numerical stability. The results of these tests are included in this report. DTIC

ISOLATION AND ANALYSIS OF KEY COMPONENTS OF SEAFLOOR RELIEF Final Technical Report, 1 Oct. 1991 - 30 Sep. 1992

Dennis E. Hayes 1992 10 p

(Contract N00014-92-J-1049)

(AD-A261635) Avail: CASI HC A02/MF A01

We are continuing to investigate several hypotheses regarding the processes that are responsible for forming the various components of seafloor relief and the composite seafloor roughness. We have put forward the hypothesis that the composite seafloor relief can be meaningfully divided into three or more distinctive spatial wavebands each of which can be related to different physical processes. Our goal is to understand the operative geological processes well enough to be able to better predict the complete seafloor/basement roughness characteristics where it has not been measured and for regions where it is difficult or impossible to measure accurately (e.g., buried basement relief). WIND-DRIVEN COASTAL GENERATION OF ANNUAL MESOSCALE EDDY ACTIVITY IN THE CALIFORNIA CURRENT Final Report, 1 Oct. 1990 - 30 Nov. 1991

Alejandro Pares-Sierra, Warren B. White, and C. K. Tai Feb. 1993 14 p

(Contract N00014-91-J-1278)

(AD-A261355) Avail: CASI HC A03/MF A01

Two candidate sources for the generation of mesoscale eddy activity in the California Current are local baroclinic instability and/or the wind stress adjacent to the coast. The latter constitutes remote forcing with eddy activity propagating westward from the coast into California Current via Rossby wave dynamics. In this study, two wind-driven models are utilized to test the relative significance of these two sources. One is an eddy resolving quasigeostrophic (QG) model, with the ability to represent baroclinic instability but not the coastal response to winds. The other is a 1 1/2-layer primitive equation (PE) model with the ability to represent the coastal response to winds but not baroclinic instability. Both models have the same spatial grid (i.e.. approximately 20 km) and are driven by the same coarse-grid wind stress forcing fields over the same one year time period (i.e. January 1987 to December 1987). The PE model is able to simulate qualitatively this distribution of the eddy variance as it appears in altimetric sea level, yielding significant coherence and phrase between model and observed sea-level residuals along longitude/time matrices at 30 deg N and 40 deg N. The QG model on the other hand, is found incapable of simulating the main features of this distribution of eddy variance. DTIC

COASTAL OCEAN PROCESSES: A SCIENCE PROSPECTUS

K. H. Brink, J. M. Bane, T. M. Church, C. W. Fairall, and G. L. Geernaert Apr. 1992 101 p

(Grant NSF OCE-91-08993)

(AD-A261702; WHOI-92-18) Avail: CASI HC A06/MF A02

CoOP (Coastal Ocean Processes) is an organization meant to study major interdisciplinary scientific problems in the coastal ocean. Its goal is to obtain a new level of quantitative understanding of the processes that dominate the transformations, transports and fates of biologically, chemically and geologically important matter on the continental margin. Central to obtaining this understanding will be advances in observing and modeling the cross-shelf component of transport. More specific objectives are to understand (1) cross-margin exchanges, (2) air-sea exchanges, (3) benthic-pelagic exchanges, (4) terrestrial inputs, and (5) biological and chemical transformations within the water column. CoOP research will be carried out primarily through a series of process-oriented field studies, each involving about two years of measurements. Each of these field studies is to be initiated and defined through a community workshop. In addition to the process studies, CoOP will also involve modeling, long time series, exploratory studies, remote sensing, technological innovation, data archiving and communications. A CoOP pilot study has been approved for

funding by the National Science Foundation, and funding will begin in 1992. The CoOP science effort is thus already underway. DTIC

INTERACTION OF AN EDDY WITH A CONTINENTAL SLOPE Ph.D. Thesis
Xiaoming Wang Sep. 1992 220 p
(AD-A261550; WHOI-92-40) Avail: CASI HC A10/MF A03

The barotropic interactions between a mesoscale eddy and a straight monotonic bottom topography are studied. Through simple to relatively complicated modeling effort, some of the fundamental properties of the interaction are investigated. The fundamental aspects of the interaction are examined using a simple contour dynamics model. With the simplest model configuration of an ideal vortex and a step topography, the basic dynamical features of the observed oceanic eddy-topography interaction are qualitatively reproduced. The results consist of eddy-induced cross-topography exchange, formation of topographic eddies, eddy propagation, and generation of topographic waves. A more complicated primitive equation model is used to investigate a mesoscale eddy interacting with an exponential continental shelf/slope topography on both f and beta-planes. The roles of the eddy size and strength and the geometry of topography are studied. It is seen that the multiple anticyclonic eddy-slope interactions strongly affect the total cross-slope volume transport and the evolution of both the original anticyclone and the topographic eddy. Since a cyclone is trapped at the slope and eventually moves on to the slope, it is most effective in causing perturbation on the shelf and slope. The responses on the shelf and slope are mainly wavelike with dispersion relation obeying that of the free shelf-trapped wave modes. It is found that the straight eddy incident is more effective in achieving large onslope eddy penetration distance than the oblique eddy incident. DTIC

A COASTAL HAZARDS DATA BASE FOR THE US EAST COAST
V. M. Gornitz, T. W. White (Oak Ridge National Lab., TN.), and R. C. Daniels (Tennessee Univ., Knoxville.) Aug. 1992 172 p
(Contract DE-AC05-84OR-21400)
(NASA-TM-108265; NAS 1.15:108265; DE93-003678; ORNL/CDIAC-45; NDP-043A; ESDP-3913) Avail: CASI HC A08/MF A02

This document describes the contents of a digital data base that may be used by raster or vector geographic information systems (GIS) and non-GIS data bases to assess the risk of coastlines to erosion or sea level rise. The data base integrates point, line, and polygon data for the US East Coast into 0.250 latitude (times) 0.250 longitude grid cells. Each coastal grid cell contains data on geology, geomorphology, elevation, wave heights, tidal ranges, shoreline displacement (erosion), and sea-level trends. These data are available as a Numeric Data Package (NDP), from the Carbon Dioxide Information Analysis Center, consisting of this document and a set of computerized data files. The documentation contains information on the methods used in calculating each variable, detailed descriptions of file contents and formats, and a discussion of the sources, restrictions, and limitations of the data. The data files are available on magnetic tape, on floppy diskettes, or through INTERNET. DOE

KINETIC STUDIES OF INTERFACIAL PHOTOCURRENTS IN PLATINIZED CHLOROPLASTS
E. Greenbaum 1992 2 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-002344; CONF-930571-1) Avail: CASI HC A01/MF A01

The present experiments focus on kinetic studies of photocurrents generated in a photobioelectrochemical cell constructed from platinized chloroplast membranes. These chloroplast membranes although separated from the CO2-reducing enzymes of the Calvin-Benson cycle, contain the full complement of photosystem 1 and 2 reaction centers along with the electron transport chain linking these two centers. The vectorial model of photosynthesis indicates that the orientation of the reaction centers in the photosynthetic membranes is such that electrons emerge from the membranes into the stroma region of the chloroplasts. Since the flattened saclike vesicles of the thylakoid membranes are topologically equivalent to spheres, it follows that, irrespective of the rotational orientation of the membranes, the photogenerated electrons emerge from the reaction centers in a radial direction away from the intra-thylakoid region. The purpose of the Search for Extraterrestrial Intelligence (SETI) Institute is to conduct and promote research related activities regarding the search for extraterrestrial life, particularly intelligent life. Such research encompasses the broad discipline of 'Life in the Universe', including all scientific and technological aspects of astronomy and the planetary sciences, chemical evolution, the origin of life, biological evolution, and cultural evolution. The primary purpose was to provide funding for the Principal Investigator to collaborate with the personnel of the SETI Institute and the NASA-Ames Research center in order to plan and develop space biology research on and in connection with Space Station Freedom; to promote cooperation with the international partners in the space station; to conduct a study on the use of biosensors in space biology research and life support system operation; and to promote space biology research through the initiation of

an annual publication 'Advances in Space Biology and Medicine'.

ACHIEVING THE PROMISE OF THE BIOSCIENCE REVOLUTION: THE ROLE OF THE FEDERAL GOVERNMENT
Dec. 1992 19 p Original contains color illustrations
(PB93-139970) Avail: CASI HC A03/MF A01

This report deals with the role of the federal government in achieving two goals: (1) promoting the health of the American people and all mankind through research in the biosciences; and (2) fostering a vigorous American biotechnology industry. These goals are inter-related. Discoveries in the biosciences are the basis for industrial development of more effective ways to prevent or treat illness, produce more nutritious foods, make use of renewable energy sources, and protect the environment. A critical factor in the continued success of America's biotechnology industry is the strength of the nation's bioscience research enterprise. Author

EFFECT OF CYTOSKELETAL REAGENTS ON STRETCH ACTIVATED ION CHANNELS Final Report, 15 Mar. 1989 - 14 Jun. 1992
Frederick Sachs 12 Nov. 1992 5 p
(Contract DAAL03-89-K-0064)
(AD-A261089; ARO-26099.9-LS) Avail: CASI HC A01/MF A01

Mechanically sensitive ion channels have been proposed to respond to membrane tension. We have developed methods to measure the membrane tension in a patch and have examine the stress strain relationship. The results show that, in general, tension is the critical variable. However, we have also found one channel in glial cells whose gating is additionally dependent upon the curvature of the membrane. Stresses in a patch caused by suction lead to lipid flow along the wall of the pipette, but the flow is constrained by the highly extensible cytoskeleton whose area elastic constant is ca. 50 dyn/cm. We developed tools to use high voltage electron microscopy to study the structure of patches and have characterized the placement of cytoskeleton, lipids, and receptors in a variety of preparations. We also developed a new algorithm to align projections for tomography in order to examine the three dimensional structure of patches. We have demonstrated mechanically induced release of calcium via stretch activated ion channels in heart cells extending work on the molecular level to the whole cell level. DTIC

ANATOMY AND PHYSIOLOGY OF PLANT CONDUCTIVE SYSTEMS
Craig McFarlane, ed. and S. Trapp, ed. 1993 42 p Repr. from Modeling Anthropogenic Organic Chemicals in Plants (New York), Marcel Decker Publishing Corp., 1993
(PB93-156032; EPA/600/A-93/017) Avail: CASI HC A03/MF A01

Mathematical models considered in the book are representations of the physical features and chemical reactions that define interactions between plants and their environment. By centering attention on equations, it is easy to lose sight of the intricate and complex nature of the problem. The particular chapter describes the anatomy of important plant features and briefly discuss some physiological principles that will help to visualize and perceive the conditions which are represented in the models. Because of the many competing interactions, the fate of chemicals in the soil/plant/air environment is not obvious. Models were thus developed to intelligently integrate available knowledge, to increase understanding of the complex interactions, to aid in presentation of plant functions, and to help make predictions about chemical fate. A method for the detection of Pseudomonas bacteria is described where an Azurin-specific antibody is employed for detecting the presence of Azurin in a test sample. The detection of the presence of Azurin in the sample is a conclusive indicator of the presence of the Pseudomonas bacteria since the Azurin protein is a specific marker for this bacterial strain.

EFFECTS OF SPACE RADIATION ON HUMORAL AND CELLULAR IMMUNITY IN RHESUS MONKEYS Final Report, May 1990 - Mar. 1991
William H. Stone and Michael L. Miller (Childrens Memorial Hospital, Chicago, IL.) Dec. 1992 21 p
(Contract F33615-87-D-0626)
(AD-A261808; AL-TR-1992-0101) Avail: CASI HC A03/MF A01

The objective of this study was to complete profiles of immune competence in rhesus monkeys more than 25 years after single exposures to protons of different energies. Access to irradiated animals provided a unique opportunity to study late effects on the immune systems of nonhuman primates; late immunological defects could be relevant to astronauts and high-flying pilots. Working with the primate model allowed us to assess the possible late effects of ionizing radiations on parameters associated with B-cell and T-cell functions. Antibody-mediated immune (AMI) function was investigated by measuring immunoglobulin (Ig) levels, hemolytic complement activity, and autoantibodies. Cell-mediated immune (CMI) function was evaluated by measuring selected T- and B-cell activities as well as responses to mitogens and interleukin production. There were no significant differences between control and irradiated animals for most parameters measured in this survey, but some reduction in spontaneous proliferation was noted in irradiated primates. With regard to late risks for humans following exposure(s) to ionizing radiations, it is encouraging that few late immunobiological effects were exhibited by primate survivors of low and intermediate doses of protons. The development of a physiological monitoring capability for the Army's advanced helicopter simulator facility is reported. Additionally, preliminary physiological data is presented. Our objective was to demonstrate the sensitivity of physiological measures in this simulator to self-reported simulator sickness. The data suggested that heart period, hypergastria, and skin conductance level were more sensitive to simulator sickness than were vagal tone and normal electrogastric activity. Author (revised)

MECHANICAL STIMULATION OF SKELETAL MUSCLE MITIGATES GLUCOCORTICOID INDUCED DECREASES IN PROSTAGLANDIN SYNTHESIS
Joseph A. Chromiak and Herman H. Vandenburgh 1993 35 p
(Grant NAG2-414)
(NASA-CR-193040; NAS 1.26:193040) Avail: CASI HC A03/MF A01

The glucocorticoid dexamethasone (Dex) induces a decline in protein synthesis and protein content of tissue cultured, avian skeletal muscle cells, and this atrophy is attenuated by repetitive mechanical stretch. Since the prostaglandin synthesis inhibitor indomethacin mitigated this stretch attenuation of muscle atrophy, the role of prostaglandins as growth modulators in these processes was examined. Dex at 10(exp -8) M reduced PGF(sub 2(alpha)) production 55 percent - 65 percent and PGE(sub 2) production 84 - 90 percent after 24 - 72 h of incubation in static cultures. Repetitive 10 percent stretch-relaxations of the non-Dex treated cultures increased PGF(sub 2(alpha)) efflux 41 percent at 24 h and 276 percent at 72 h and increased PGE(sub 2) production 51 percent at 24 h and 236 percent at 72 h. Mechanical stimulation of Dex treated cultures increased PGF(sub 2(alpha)) production 162 percent after 24 h, thus returning PGF(sub 2(alpha)) efflux to the level of non-Dex treated cultures. At 72 h, stretch increased PGF(sub 2(alpha)) efflux 65 percent in Dex treated cultures, but PGF(sub 2(alpha)) production was 45-84 percent less than non-Dex treated cultures. Mechanical stimulation of Dex treated cultures increased PGE(sub 2) production at 24 h, but not at 72 h. Dex reduced prostaglandin H synthase (PGHS) activity in the muscle cultures by 70 percent after 8 - 24 h of incubation, and mechanical stimulation increased PGHS activity of the Dex treated cultures by 98 percent. It is concluded that repetitive mechanical stimulation attenuates the catabolic effects of Dex on cultured skeletal muscle cells in part by reversing the Dex-induced declines in PGHS activity and prostaglandin production. BIOMAGNETIC LOCALIZATION FROM TRANSIENT QUASI-STATIC EVENTS
J. C. Mosher, R. M. Leahy, and P. S. Lewis 1993 5 p Presented at the IEEE International Conference on Acoustics, Speech, and Signal Processing, Minneapolis, MN, 27-30 Apr. 1993
(Contract W-7405-eng-36)
(DE93-007328; LA-UR-93-402; CONF-930489-1) Avail: CASI HC A01/MF A01

Sensory stimuli, such as auditory, visual, or somatosensory, evoke neural responses in very localized regions of the brain. A SQUID biomagnetometer can measure the very weak fields that are generated outside of the head by this response. A simple source and head model of current dipoles inside a conducting sphere is typically used to interpret these magnetic field measurements or magnetoencephalogram (MEG). Locating dipole sources using data recorded from an array of biomagnetic sensors is distinguished from conventional array source localization techniques by the quasi-static transient nature of the data. Here, the basic MEG model is reviewed, then a localization example is given to motivate the need for partitioning the data to improve estimator performance. Tune-eigenspectrum analysis is introduced as a means of partitioning and interpreting spatio-temporal biomagnetic data. Examples using both simulated and somatosensory data are presented. DOE

The use of artificial lens implants to correct for aphakia has become

increasingly prevalent in the United States. This study analyzes the distribution of intraocular lens (IOL) implants in the civil airman population by type (unilateral, bilateral), class of medical certificate, and gender for a 4-year period (1982-85). Medical records were evaluated for all certified airmen who were carrying pathology codes for aphakia artificial lenses was higher for bilateral, second-class medical certificate holders, and female aphakics. However, the incidence of total and unilateral artificial lens implants declined in 1985. The implications of the study's findings for aeromedical certification are discussed. A change in the methods used to evaluate trends in the use of IOL in the airman population is recommended.

This final report summarizes investigations conducted during this project. During the course of the project, investigations were undertaken to address the following objectives: (1) to develop exposure systems and methodology to deliver pure, stable atmospheres of HF, HBr, or HCl to laboratory rats; (2) to determine the toxicological equivalency of inhaled HF, HBr, and HCl in the upper and lower respiratory tract; (3) characterize the anatomical sites of injury caused by HF, HCl, and HBr when inhaled at high mass concentrations through the nasal (NB) and oral (MB) pathways; (4) to assess the relative toxicities of the above halides when inhaled at high mass concentrations during mouth and nose breathing; (5) to characterize the upper and lower respiratory tract lesion(s) produced by HCl inhalation in the nose breathing (NB) and mouth breathing (MB) rats during CO2-induced increased minute ventilation; (6) to examine the toxicity of HF when administered directly into the rat's lung; (7) to determine if work performance incapacitation occurs after acute high concentration inhalation of HCl via the nose (NB) or the mouth (MB); (8) to assess post-exposure exercise as a potentiator of the severity of expression of halide-induced respiratory tract injury; and (9) to initiate studies to determine whether or not lung injury becomes more pronounced after halides are breathed in combination with a particulate phase. Metabolic perturbation and enzyme structure-function studies are presented. We have now almost completed our investigation of the structure-function relationships that are thought to be involved with regulating the activity of phosphofructokinase (PFK) in vivo. Specifically, we set out to study how alterations in quaternary structure account for enzyme inhibition in red blood cells under cold, acidotic conditions. Prior in vitro studies have shown that phosphofructokinase from erythrocytes (and several other mammalian cells and tissues) dissociates from active tetrameres into inactive dimers and monomers at low Ph. In addition, we have previously demonstrated that this reversible phenomenon accounts for the inhibition of PFK activity in vivo in ischemic myocardium. DTIC

This project was designed to characterize olfactory tissue-specific proteins previously identified with a library of monoclonal antibodies raised against frog olfactory cilia. First, we showed that our olfactory tissue-specific monoclonal antibodies all recognize different molecular forms of the same protein. We named this protein 'olfactomedin'. We then proceeded to purify olfactomedin and characterize it biochemically and immunohistochemically. We showed that olfactomedin is produced only in olfactory tissue by sustentacular cells and Bowman's glands and that it is deposited in the lower mucus layer of olfactory neuroepithelium. Next, we extracted mRNA from olfactory tissue and constructed a cDNA library. We obtained partial sequence information of the N-terminus of purified olfactomedin and used these data to design a degenerate oligonucleotide probe for the identification of a full-length cDNA clone which encodes olfactomedin. This clone was sequenced and found to encode a 448 amino acid protein preceded by a leader peptide of 16 amino acids. Analysis of the sequence showed no homologies with any known protein. Examination of its amino acid sequence by Chou-Fasman analysis in combination with biochemical and immunochemical evidence obtained previously enabled us to construct a model for olfactomedin which identifies this protein as a novel olfactory tissue-specific extracellular matrix protein, which forms the main structural component of the extracellular mucous matrix of olfactory neuroepithelium and which may trigger the growth and differentiation of the dendritic knob and its olfactory cilia that house the olfactory transduction machinery.

The purpose of this study was to formulate and to evaluate rehydration drinks, which would restore total body water and plasma volume (PV), for astronauts to consume before and during extravehicular activity, a few hours before reentry, and immediately after landing. In the first experiment (rest, sitting), five healthy men (23-41 yr), previously dehydrated for 24 hr., drank six (1a, 2, 4, 5, 6, 7) fluid formulations (one each at weekly intervals) and then sat for 70 min. Pre-test PV were measured with Evans blue dye and changes in PV were calculated with the hematocrit-hemoglobin transformation equation. This rest experiment simulated hypohydrated astronauts preparing for reentry. The second experiment (exercise, supine) followed the same protocol except four healthy men (30-46 yr) worked for 70 min. in the supine position on a cycle ergometer at a mean load of 71 +/-1 percent of their peak aerobic work capacity. This exercise experiment simulated conditions for astronauts with reduced total body water engaging in extravehicular activity. Author (revised)

Standard refractive error correction options for the M-43 protective mask have proven to be incompatible with the Helmet Display Unit (HDU) component of the AH-64 Apache Integrated Helmet and Display Sighting System (IHADSS). Glue-on and outsert packages push the HDU, a Maxwellian-view virtual imaging system, far enough from the spectacle-wearing aviator's eye to significantly reduce the available field-of-view. Consequently, portions of critical peripheral instrumentation and weapon system overlays cannot be visualized. In November 1988, the U.S. Army Aeromedical Research Laboratory (USAARL) initiated the AH-64 contact lens research protocol to provide both an interim readiness fix and to develop a comprehensive database on contact lens wear in a variety of environments. The protocol was organized from three perspectives with

concerns directed toward operational and flight safety, ocular health, and corneal physiology issues, and concluded at the end of September 1991. Fundamental operational and safety data were chronicled, along with written questionnaires, to assess subjective effectiveness of routine contact lens use. Ocular health complications were collated from the aviation medicine, optometric, and ophthalmological communities. Clinical and physiological data were gathered by one USAARL optometrist, and two contract civilian optometrists and their supporting technicians. DTIC

ORGANIZATIONAL POLITICS, PARTICIPATION IN DECISION-MAKING, AND JOB SATISFACTION Final Report
L. A. Witt Apr. 1992 15 p
(FAA Proj. AM-C-92-HRR-122)
(DOT/FAA/AM-92/17) Avail: CASI HC A03/MF A01

The study tested two hypotheses: (1) that organizational politics as measured by the Kacmar and Ferris (1991) Perceptions of Organizational Politics Scale would be negatively related to feelings of job satisfaction; and (2) that participation in decision-making (PDM) would moderate that relationship. In line with concerns for dispositional affect as a contributor to method variance and the possibility that biodata may explain some of the effects of organizational politics and PDM on job satisfaction, dispositional affect and biodata variables were included in the analyses. Hierarchical moderated multiple regression analyses conducted on data collected from 1,083 Federal employees confirmed the hypotheses. Author

A LONGITUDINAL EXAMINATION OF APPLICANTS TO THE AIR TRAFFIC CONTROL SUPERVISORY IDENTIFICATION AND DEVELOPMENT PROGRAM Final Report
Jennifer G. Myers, ed. Apr. 1992 57 p
(FAA Proj. AM-C-92-HRR-125)
(DOT/FAA/AM-92/16) Avail: CASI HC A04/MF A01

The Federal Aviation Administration began development of an extensive longitudinal database on its air traffic controller workforce following the strike of 1981. Since that time, data have been collected on thousands of air traffic controllers, spanning a period which covers their application to the federal government for employment to their achievement of a first-line supervisor position. This collection of papers examines a subset of air traffic control specialists who have completed the agency's supervisor selection program, beginning with their performance on the Office of Personnel Management test battery and other cognitive tests administered prior to completion of the air traffic controller Screen Program. Measures of academic, laboratory, and overall Screen performance were examined in relationship to aspects of performance in the supervisor selection program. Field training profiles were analyzed to determine differences between successful and unsuccessful supervisor selection program candidates and relationship with selection program performance. Finally, performance in the supervisor selection program was compared for those who were selected as first-line supervisors and those who were not. Author

PROCEEDINGS OF WORKSHOP 1: THE HUMAN BRAINMAP DATABASE Final Report, 15 Apr. 1991 - 31 Aug. 1992
Peter T. Fox and Jack L. Lancaster 17 Feb. 1993 89 p Workshop held in San Antonio, TX, 29 Nov. - 1 Dec. 1991
(Contract N00014-91-J-1903)
(AD-A260720) Avail: CASI HC A05/MF A01

The Human BrainMap Database is a software environment for meta-analysis of functional brain mapping experiments. In brief, BrainMap relates brain locations with behavioral functions. For any brain region, the behavioral conditions associated with that region can be returned. Conversely, for any behavioral function, the brain regions supporting that behavior can be retrieved. BrainMap is composed of three main parts: a relational database, graphical user interface (GUI), and a data-entry interface. BrainMap's database is constructed in a natural hierarchy. The highest level is the paper. Each paper is divided into one or more experiments. An experiment is a grouping (typically a pairing) of behavioral conditions

for which differentially activated locations are reported. Behavioral conditions are specified for each experiment. Methodological details are specified for each experiment, including imaging modality, tracer, patient population, etc. Each experiment reports one or more activated locations, the lowest level of the hierarchy. Each location (i.e., each x-y-z coordinate) carries its links up the hierarchy, allowing formation at the experiment and paper levels to be rapidly retrieved. DTIC

EVALUATION OF LENS DISTORTION ERRORS IN VIDEO-BASED MOTION ANALYSIS

Jeffrey Poliner (Lockheed Engineering and Sciences Co., Houston, TX.), Robert Wilmington (Lockheed Engineering and Sciences Co., Houston, TX.), Glenn K. Klute, and Angelo Micocci (Lockheed Engineering and Sciences Co., Houston, TX.) May 1993 41 p

(Contract NAS9-17900)

(NASA-TP-3266; S-721; NAS 1.60:3266) Avail: CASI HC A03/MF A01

In an effort to study lens distortion errors, a grid of points of known dimensions was constructed and videotaped using a standard and a wide-angle lens. Recorded images were played back on a VCR and stored on a personal computer. Using these stored images, two experiments were conducted. Errors were calculated as the difference in distance from the known coordinates of the points to the calculated coordinates. The purposes of this project were as follows: (1) to develop the methodology to evaluate errors introduced by lens distortion; (2) to quantify and compare errors introduced by use of both a 'standard' and a wide-angle lens; (3) to investigate techniques to minimize lens-induced errors; and (4) to determine the most effective use of calibration points when using a wide-angle lens with a significant amount of distortion. It was seen that when using a wide-angle lens, errors from lens distortion could be as high as 10 percent of the size of the entire field of view. Even with a standard lens, there was a small amount of lens distortion. It was also found that the choice of calibration points influenced the lens distortion error. By properly selecting the calibration points and avoidance of the outermost regions of a wide-angle lens, the error from lens distortion can be kept below approximately 0.5 percent with a standard lens and 1.5 percent with a wide-angle lens. A COGNITIVE ARCHITECTURE FOR HUMAN PERFORMANCE PROCESS MODEL RESEARCH Interim Report, Dec. 1991 - Jul. 1992

Michael J. Young Nov. 1992 38 p

(AD-A261040; AL-TP-1992-0054) Avail: CASI HC A03/MF A01

This Technical Paper proposes a new cognitive architecture for human performance process (HPP) model research. HPP models are engineering models of human performance. They represent the human information-processing system as a series of subsystems consisting of input and output, memory, and processing subsystems. HPP models are used in engineering studies of new systems where the goal of the study is to predict human performance. This report proposes a new cognitive architecture for HPP model research. This new architecture is based upon the holon theory of mind previously proposed by Arthur Koestler. The holon theory of mind proposes that mind is both highly modular and hierarchically organized. The report provides an overview of HPP model research, describes the holon theory of mind, and discusses how this theory can form the basis of a new cognitive architecture for HPP model research. CONTRIBUTION OF PERSONALITY TO THE PREDICTION OF SUCCESS IN INITIAL AIR TRAFFIC CONTROL SPECIALIST TRAINING Final Report

David J. Schroeder, Dana Broach, and Willie C. Young Apr. 1993 32 p

Presented at the 34th Annual Meeting of the Aerospace Medical Association, Miami, FL Sponsored by Office of Aviation Medicine

(DOT/FAA/AM-93/4) Avail: CASI HC A03/MF A01

Reviews have consistently concluded that the validity of personality as a predictor of job performance is low. However, a 1991 meta-analysis of studies of personality and job performance demonstrated the utility of the 'Big Five' model of personality in personnel selection and training. This study was designed to evaluate the utility of personality in predicting student success in the FAA's Air Traffic Control Specialist (ATCS) Nonradar Screen Program ('the Screen'). The Screen follows the miniature training, testing, and evaluation paradigm, in which individuals with no prior knowledge of the occupation are taught critical aspects of the job and then assessed on a pass/fail basis for their potential to succeed as controllers. The NEO personality Inventory was administered to 723 men and 307 women at entry into the 9-week Screen. NEO-PI scale scores and cognitive aptitude measures were used to predict final composite scores (COMP) of students. Men and women air traffic students exhibited lower average scores in Neuroticism, higher average scores in Extroversion, Openness to Experience, and Conscientiousnous, and no difference on Agreeableness when compared to normative samples. Correlations between the personality scales and COMP were low for both sexes, ranging from .000 with Impulsiveness, a facet of Neuroticism, to -0.148 with Excitement-seeking, a facet of the Extraversion dimension. Despite the low zero-order correlations, several of the personality facets proved useful in a regression equation, explaining an additional 3 percent of variance in performance over that explained by cognitive aptitude measures. These included the following: Excitement-seeking, Fantasy, Activity, and Ideas. While these results were not entirely consistent with Barrick and Mount (1991), they do offer some support for the role of personality variables in the prediction of success in the ATCS Screen. Continued research is needed to assess the relationship of theoretically-based measures of personality to success on the job over time. Author (revised)

VISUAL PERCEPTION OF ELEVATION Annual Report, 1 Jan. - 31 Dec. 1992

Leonard Matin 25 Jan. 1993 12 p

(Grant AF-AFOSR-0146-91)

(AD-A261394; Rept-002; AFOSR-93-0084TR) Avail: CASI HC A03/MF A01

The work at the Columbia laboratory concentrated on two matters: (1) expansion of the work on uncovering the laws of spatial summation between and within members of parallel line sets with regard to the influence on the setting of visually perceived eye level (VPEL); and (2) initial work on the separation of components of the body-referenced mechanism and to determine their separate influence on VPEL. The work on summation was reported at 4 presentations at professional meetings in 1992 and a fifth set of experiments has been submitted for presentation in 1993. The completed experimental work on the body-referenced mechanism has been submitted for presentation in 1993. In addition to the above, at Columbia we have begun work in which eye movements are being measured (scleral search coil technique) in conjunction with variation of visual field pitch with the first interest in determining whether a subject's setting of eye level to VPEL is differently influenced by the visual field than is the discrimination of VPEL. NEUROPSYCHOLOGICAL COMPONENTS OF OBJECT IDENTIFICATION Final Technical Report, Dec. 1990 - Nov. 1992

Stephen M. Kosslyn 29 Jan. 1993 19 p

(Grant AF-AFOSR-0100-91)

(AD-A261449; AFOSR-93-0070TR) Avail: CASI HC A03/MF A01

The research supported by this grant focused on the structure of high-level visual processing. Five types of research were conducted: (1) We performed case studies of individual brain-damaged patients. We found evidence that curved edges are processed separately from straight edges and that location information sometimes can be used to encode some characteristics of shape. (2) We tested groups of brain-damaged patients with specific types of lesions. We found evidence that metric information may be used to encode spatial categories (such as above/below), and that imagery may involve some structures that are intact even when the visual field is disrupted. (3) We developed a computerized visual/spatial test battery, and administered it to a group of 19 brain-damaged patients. The results indicate that most of the visual/spatial abilities we examined can be impaired independently, suggesting that at least some distinct subsystems carry out each ability. (4) We implemented computer models and found support for the distinction between subsystems that compute two distinct kinds of spatial relations (metric and category). (5) Some of the tasks we developed to study deficits in brain-damaged patients were

used to study the visual-spatial abilities of Air Force pilots; we found that pilots are particularly good at mental rotation and encoding metric distance information. DTIC

NEURAL BASIS OF MOTION PERCEPTION Annual Report, 1 Apr. 1991 - 31 May 1992
V. S. Ramachandran 31 May 1992 5 p
(Grant AF-AFOSR-0414-89)
(AD-A261452; AFOSR-93-0050TR) Avail: CASI HC A01/MF A01

Our research is concerned with 'high level' vision with a strong biological slant. The last two or three decades have seen breathtaking progress in the three disciplines--cognitive psychology, AI, and visual neurophysiology--but they have been pursued more or less independently. We believe that the time is now ripe for forging links between these disciplines for an integrated approach to vision. We have had two goals in mind: (1) to develop conceptual links between neurophysiology and perception; and (2) to develop specific tests for computational models of human vision. Our research has called into question several widely accepted dogmas concerning the mechanisms of early vision. Also, we have been able to discover several novel visual phenomena (e.g., motion capture, stereo-capture, etc.) and have identified a wide range of new 'natural constraints' that govern the perception of shape from shading structure from motion and motion correspondence. Also, we have discovered striking perceptual correlates of several well-known physiological observations (e.g., 'phantom contours'-stimuli which selectively activate the magnocellular pathway). DTIC

FACILITATION AND INTERFERENCE IN IDENTIFICATION OF PICTURES AND WORDS Annual Report, 1 Dec. 1991 - 30 Nov. 1992
Joan G. Snodgrass 10 Jan. 1993 16 p
(Contract F49620-92-J-0119)
(AD-A261484; AFOSR-93-0085TR) Avail: CASI HC A03/MF A01

This research is concerned with facilitation and interference in the identification of pictures and words. We study facilitation by presenting subjects with fragmented stimuli to identify during study and then test the ability of various types of study stimuli to prime or improve performance on the same stimuli presented again. An important finding from our previous research is that subjects show more priming when they study a picture which is moderately fragmented during study than one which is either very fragmented or almost intact. We accounted for this phenomenon by the perceptual closure hypothesis, which says that experiencing perceptual closure, or completion of an incomplete figure during a study episode, has the most facilitative effect on subsequent identification. We study interference by presenting more degraded versions of a picture or word just prior to the identification test. Perceptual interference is generally observed if a picture or word is preceded by more fragmented versions of itself just prior to identification. Much of our work on this aspect of the research concerns discovering the reason for the perceptual interference. DTIC

SPONTANEOUS DISCOVERY AND USE OF CATEGORICAL STRUCTURE Annual Technical Report, 15 Jan. 1992 - 14 Jan. 1993
John P. Clapper and Gordon H. Bower 15 Feb. 1993 31 p
(Grant AF-AFOSR-0144-91)
(AD-A261658; AFOSR-93-0093TR) Avail: CASI HC A03/MF A01

These experiments investigated unsupervised category learning using tasks in which subjects attempted to memorize the features of training instances from two contrasting categories. On each trial, subjects studied a verbal feature list (training instance) for 24 seconds, after which they were given multiple choice recognition tests to evaluate their memory for each list item. The amount of time spent looking at each feature during the study phase, and the accuracy of recognition during the test phase, provided two separate indices of unsupervised learning on each trial. The main independent variable in these experiments was the specific sequence in which instances from the two categories were presented. The effects of these sequence manipulations on learning provided strong evidence for the use of an explicit, non-incremental, category invention process to capture the consistent structure of the stimulus domain. The present experiments also showed the selective encoding process and enhanced memory for instances predicted by standard, schema-based, theories of learning. DTIC

PHYSIOLOGICAL INDICES OF MENTAL WORKLOAD Interim Technical Report, 15 Dec. 1991 - 14 Dec. 1992
Alan Gevins and H. M. Leong 14 Dec. 1992 7 p
(Contract F49620-92-C-0013)
(AD-A261692; AFOSR-93-0086TR) Avail: CASI HC A02/MF A01

We are working on an enabling technology to facilitate the development of physiological indices of mental workload that could be used in high performance aircraft. To date, we have designed and implemented the core components of a neural-network based algorithm for deriving continuous mental workload indices from continuous recordings of brain, scalp muscle, eye and heart electrical activity. We have also designed an experiment to test the adequacy of this algorithm, and have developed technologies to perform the experiment including: (1) designing a task battery to initially test the ability of the network algorithm to generalize across cognitive functions relevant to piloting aircraft; and (2) implementing a software library that could be used to efficiently present the task stimuli using the same personal computer which also collects 32 channels of electrophysiological data. We have tested the integrated system and have found it capable of providing accurate timing of task stimuli, subject responses, and electrophysiological data. DTIC

DURATION OF ALPHA SUPPRESSION INCREASES WITH ANGLE IN A MENTAL ROTATION TASK Report, 1 Feb. 1992 - 14 Feb. 1993
C. M. Michel, L. Kaufman, and S. J. Williamson 1 Feb. 1993 27 p
(Grant AF-AFOSR-0221-90)
(AD-A261592; Rept-92-6; AFOSR-93-0055TR) Avail: CASI HC A03/MF A01

Magnetic and electric recordings of average power within the restricted alpha band (10-12 Hz) were made over the parietal and occipital areas of the human scalp while subjects were engaged in the mental imagery task of comparing an object with one previously seen but rotated and perhaps also mirror reflected. Alpha power was found to be suppressed while the subjects were engaged in the comparison, and the duration of suppression increased with the minimum rotation angle to achieve a match. This is additional evidence that the visual cortex is engaged in the process of mental imagery. Moreover, for large rotation angles, where the task is markedly more difficult, a shift in the spatial pattern of suppression indicates that the left parietal area of the cortex becomes involved. IMAGING REGIONAL CHANGES IN THE SPONTANEOUS ACTIVITY OF THE BRAIN: AN EXTENSION OF THE MINIMUM-NORM LEAST-SQUARES ESTIMATE Manuscript Report, 1 Feb. 1992 - 14 Feb. 1993
Jia Z. Wang, Lloyd Kaufman, and Samuel J. Williamson 20 Jan. 1993 16 p
(Grants AF-AFOSR-0401-91; AF-AFOSR-0221-90)
(AD-A261593; Rept-92-5; AFOSR-93-0054TR) Avail: CASI HC A03/MF A01

A method was developed to determine the distribution of average spontaneous neuronal activity across the cerebral cortex from measurements of the field pattern across the human scalp. Computations of the mean short-term power, as well as the covariance between pairs of sensors, provide sufficient information to obtain a best estimate for the distribution of mean short-term image current power, as well as the covariance of image current between different locations on cerebral cortex. This method

has applications for determining the spatial locations of alpha power suppression as regions of cortex participate in sensory or cognitive functions. DTIC

COMPARATIVE ANALYTICAL STUDY OF EVOKED AND EVENT RELATED POTENTIALS AS CORRELATES OF COGNITIVE PROCESSES Final Technical Report, 1 Feb. 1991 - 31 Oct. 1992
Theodore H. Bullock 21 Dec. 1992 5 p
(Grant AF-AFOSR-0191-91)
(AD-A261388; AFOSR-93-0043TR) Avail: CASI HC A01/MF A01

This project permitted collaboration between Prof. Erol Basar in Lubeck and Dr. Bullock on new views and analyses of cognitive Event Related Potentials (ERP's), evoked oscillations (induced Rhythms, IR's) and their relations to the EEG. ERP's have been found for the first time in nonmammalian models (fish, turtles), especially Omitted Stimulus Potentials (OSP's) and oddball ERP' and Mismatch Potentials. To compare the dynamics of these models with human ERP's, a new series of human subjects has been run, extending the range of interstimulus intervals; this showed two types of OSP with distinct dynamics - including a short ISI type not heretofore recognized. Basar and Bullock co-edited a book on a new theme: Induced Rhythms in the Brain (Birkhauser Boston, 1992), with 22 chapters by invited experts. The phenomenon of triggered or modulated oscillations has been known for more than 50 years but not been recognized or studied as a category of brain responses; it is now under active investigation in ours and several other laboratories as a possible correlate of certain kinds of cognition. COORDINATED ACTION IN 3-D SPACE Annual Report, 15 Jan. 1992 - 14 Jan. 1993
Robert M. Steinman 24 Feb. 1993 7 p
(Grant AF-AFOSR-0124-91)
(AD-A261418; AFOSR-93-0136TR) Avail: CASI HC A02/MF A01

This grant: (1) tests alternative hypotheses about the mechanism that controls gaze-shifts when nearby objects are manipulated: Two quite different mechanisms have been proposed, namely, on-line feedback, and learned, preplanned patterns of coordinated movements, and (2) studies the speed and accuracy of visually-guided hand movements and the correlation of these performance measures with binocular gaze-errors. The latter studies seek to determine how accurate binocular fixation must be to assure rapid and accurate manual performance in nearby 3-D space. The answer to this (and derivative questions) is not known because, until recently, binocular gaze-errors could not be measured accurately when nearby objects were handled by a subject free to move naturally. During this past year, a unique movement monitoring instrument (the Maryland RFM) was used to make the first measurements that can be used to answer these questions. More than 200 Mb of eye and head movement data were recorded, and detailed analyses are underway. Arrangements have been made to disseminate the answers obtained widely at a number of international conferences during the remaining months of 1993. Manuscripts testing models of shape and size perception and reading of unspaced texts have been in preparation for submission publication soon. DTIC

RECEPTORAL AND NEURAL ALIASING Final Report, 1 Nov. 1989 - 30 Apr. 1992
Robert A. Smith 30 Jan. 1993 46 p
(Grant AF-AFOSR-0126-89)
(AD-A261438; AFOSR-93-0060TR) Avail: CASI HC A03/MF A01

This project saw some unexpected successes, and some even more unexpected failures. Chief among the latter was our total failure to replicate Williams' observations of receptoral aliasing, either in the fovea or the parafovea. Despite much communication between us and Williams, no explanation of this discrepancy has been found. We present substantial evidence below to eliminate the possibility of technical failure in our experiments. Unable to study aliasing directly, we pursued a very different approach to the problems of retinal geometry and aliasing: we studied methods to directly map the parafoveal visual field into its constituent summation areas (presumably receptive fields). Although we have not fully solved the very difficult problem of eye-movements, several successful studies were performed, notably: (1) the development of a precise new method for measuring fixation accuracy using afterimages, and (2) studies of spatial summation for isoluminant spots in the parafovea. In addition, a computer model was designed that produces sample ganglion cell lattices and models the process of chromatic identification. Finally, we diverged considerably from the original focus of the project to design what we believe to be the most powerful stimulus display for visual research currently available. This is now a commercial product, showing both scientific and financial success. DTIC

NEUROMAGNETIC INVESTIGATION OF CORTICAL REGIONS UNDERLYING SHORT-TERM MEMORY Technical Report, 1 Jul. 1991 - 30 Jun. 1992
Z. L. Lu, S. J. Williamson, and L. Kaufman 20 Dec. 1992 8 p
(Grant AF-AFOSR-0401-91)
(AD-A261445; Rept-92-4; AFOSR-93-0056TR) Avail: CASI HC A02/MF A01

Magnetic source imaging (MSI) makes it possible to identify the cortical area in the human brain whose activity reflects the decay of sensory storage of information about sounds (echoic memory). The lifetime for decay of the neuronal activation trace in primary auditory cortex is found to range from 0.8 sec to 3.4 sec for the subjects studied. Extensive behavioral studies that determine the duration of memory for the loudness of a tone show that these physiological measures predict the lifetime of echoic memory to within the uncertainty of 0.2 sec for each of the subjects. INITIAL EXPERIMENTS WITH A MYOELECTRIC-BASED MUSCLE SENSOR
J. F. Jansen 1992 21 p Presented at the Institute of Electrical and Electronics Engineers International Conference on Robotics and Automation, Atlanta, GA, 2-7 May 1993
(Contract DE-AC05-84OR-21400)
(DE92-016034; CONF-930519-1) Avail: CASI HC A03/MF A01

This paper describes initial experiments in which a myoelectric-based

sensor is used to measure local muscle activity in the human body -- specifically the hand muscles. Applications of this sensor are twofold: (1) to quantify the voluntary muscular activity of specific muscles for human factors studies and (2) to allow a human operator to control a mechanical hand in teleoperation mode. Discussions are focused mainly on the measurement of muscle activity and how it relates to controlling a mechanical hand. Supportive experimental results are given. DOE

A HEAT TRANSFER ANALYSIS OF A MOBILE VEHICLE RADIATION-SHIELDED OPERATOR COMPARTMENT
K. W. Snyder Dec. 1992 19 p
(Contract DE-AC04-76DP-00789)
(DE93-007428; SAND-92-2392) Avail: CASI HC A03/MF A01

Solar heat gain inside a radiation-shielded forklift operator compartment can be a significant problem due to the 'greenhouse effect'. Battery power prohibits the use of a refrigerant type of air-conditioning system, which limits the interior temperature to be approximately equal to the outside ambient temperature through alternative cooling methods. A heat transfer analysis is performed to determine the amount of solar heat gain in this type of mobile vehicle shelter. Various results are presented that depend on exterior surface finish and temperature difference between inside and outside ambient. An amount of forced air flow along with several design recommendations are then specified to rid the compartment of this excess heat. DOE

HUMAN FACTORS ENGINEERING: A KEY ELEMENT OF INSTRUMENTATION AND CONTROL SYSTEM DESIGN
H. E. Knee 1992 10 p Presented at the 39th International Instrumentation Symposium, Albuquerque, NM, 2-6 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-006731; CONF-930561-1) Avail: CASI HC A02/MF A01

Human factors engineering (HFE) has been in existence for a number of decades. Up until recently, however, its application to the design and operation of complex process control environments has been relatively conservative. In the nuclear industry, it took a major accident such as that at Three Mile Island - Unit 2 (TMI-2) to focus attention on the need for systematically accounting for the roles of humans in the control and maintenance of nuclear power plants (NPPs). Since TMI, the nuclear industry has made significant strides in fostering the use of HFE principals. This progress has been slowed to some degree due to the relatively anemic state of the US commercial nuclear power industry; however, new evolutionary and revolutionary nuclear design concepts are utilizing HFE principals and supporting research for advanced HFE concepts. Furthermore, a new Department of Energy (DOE) standard on HFE design criteria is being developed. Since instrumentation and controls (I&C) provide the interface between humans and the systems to be monitored, diagnosed and controlled, much of the HFE work is key to successful I&C. This paper will discuss HFE in the nuclear industry, its recent role in nuclear I&C, and will discuss recent applications and future directions. DOE

HELMETED HEAD AND NECK DYNAMICS UNDER WHOLE-BODY VIBRATION Ph.D. Thesis
Barclay Phelps Butler 1992 165 p
Avail: Univ. Microfilms Order No. DA9303701

The military aviator's helmet functions as both protective gear and as an equipment mounting platform for devices that enhance aviator performance. These devices include night vision goggles, head-up displays, sighting systems, and other gear such as multiple visors and chemical protective masks. This additional equipment alters the helmet mass and center of mass, which in turn, increases the load on the muscles of the neck. Sagitally symmetric changes in head supported mass (M) and center of mass (CM) for effects on head and neck posture, acceleration, and neck myoelectric responses under whole-body vibration are investigated. Twelve volunteer male aviators were exposed to short duration axially swept sinusoidal vibration while wearing twelve different helmet configurations. These configurations consisted of three masses of 2, 3, and 4 Kg, and four center of masses of -2, 0, 2 and 4 cm measured relative to the head center of mass in the Anterior/Posterior (AP) direction. Acceleration measurements were made obtaining pitch, AP, and axial motion at T1 and the AO complex. Postural measurements were made using high speed video recordings of the subject's profile. Myoelectric responses were measured using bipolar surface electrodes placed over the right and left infrahyoid, sternocleidomastoid, splenius capitus, and trapezius muscles. Results showed that postural static moments remained constant with no significant changes in head, neck, or trunk angle as a function of vibration frequency, M, or CM parameters. Acceleration measurements showed significant increases in head pitch acceleration at resonance, but no changes in resonant frequency, for changes in M and CM. Consistent resonant frequencies suggest the head and neck system is not a passive system but is actively controlled by the muscles of the neck. Myoelectric responses in the neck showed significant increases in peak RMS activity for posterior muscles and were highly correlated with head pitch acceleration (r greater than 0.80). Force calculations about the combined head and helmet center of mass were correlated (r greater than 0.85) with calibrated posterior neck muscle responses. Acceleration, myoelectric, and force calculation results suggest that significant differences are seen in the responses when added helmet mass exceeds 82 plus or minus 23 N cm relative to the AO complex. Dissert. Abstr.

ASSESSING PATTERNS OF CHANGE IN ANTHROPOMETRIC DIMENSIONS: SECULAR TRENDS OF US ARMY FEMALES, 1946-1988 Final Report, 1 Oct. 1991 - 31 Aug. 1992
Thomas M. Greiner and Claire C. Gordon Jan. 1993 75 p
(AD-A260869; NATICK/TR-93/013) Avail: CASI HC A04/MF A01

This report presents an analysis of data gathered in 1946, 1977, and 1988 anthropometric surveys of U.S. Army women to assess long-term changes in body dimensions. Fifteen dimensions are analyzed for two racial/cultural groups: Whites and Blacks. The results of these analyses describe trends that are slow, erratic, and yet statistically significant as linear models. Several hypotheses, drawn from conventional explanations of secular trends, are tested against the anthropometric trends observed in Army women. The application of these hypotheses, however, was deemed to be either inappropriate for these data or unsatisfactory in the ability to explain the observed phenomenon. It is concluded that shifting cultural forces that influence which women join the Army are the most likely cause of the observed patterns. Because these cultural actions have undergone so much change in the last half of the 20th century, it is impossible to establish a basis for predicting the anthropometric dimensions of future populations. Therefore, it is recommended that race-specific data from the most recent anthropometric survey of Army women (1988) be utilized with appropriate race-specific weights to predict Army women's body dimension values in the near future. VISUAL PROCESSING OF OBJECT VELOCITY AND ACCELERATION Annual Technical Report, 16 Jan. 1992 - 15 Jan. 1993
Suzanne McKee 14 Feb. 1993 3 p
(Contract F49620-92-J-0156)
(AD-A261048; AFOSR-93-0134TR) Avail: CASI HC A01/MF A01

The visual system can use local speed information to determine whether one surface or two transparent surfaces are visible. The local speed signals are very noisy, so a large difference in speed is necessary to produce surface segregation. Once the segregation has occurred, the visual system then integrates the local speed signals associated with each surface to improve the precision of the speed information. To study this phenomenon, speed discrimination was measured for a display composed of random dots all moving in one direction, but at two different speeds. When the speeds were sufficiently different to create the perception of two transparent planes, speed discrimination was as precise for either of the two speeds as when each was viewed alone. The local motion vectors specifying the two speeds had to be present simultaneously to produce segregation (and good speed discrimination). If all dots alternated rapidly between the two speeds in synchrony, no segregation was observed. On the other hand, asynchronous alternation, in which different subsets of dots changed speed in every frame, produced excellent segregation. DTIC

MEASURES OF USER-SYSTEM INTERFACE EFFECTIVENESS: AN ENCODING SCHEME AND INDICATORS FOR ASSESSING THE USABILITY OF GRAPHICAL, DIRECT-MANIPULATION STYLE USER INTERFACES
Donna L. Cuomo and Charles D. Bowen Jan. 1993 106 p
(AD-A260606; MTR-92B0000047V3) Avail: CASI HC A06/MF A02

The purpose of this MITRE Sponsored Research project was to develop methods and measures for evaluating user-system interface effectiveness for command and control systems with graphical, direct manipulation style interfaces. Due to the increased use of user interface prototyping during concept definition and demonstration/validation phases, the opportunity exists for human factors engineers to apply evaluation methodologies early enough in the life cycle to make an impact on system design. Understanding and improving user-system interface (USI) evaluation techniques is critical to this process. In 1986, Norman proposed a descriptive 'stages of user activity' model of human-computer interaction (HCI). Hutchins, Hollan, and Norman (1986) proposed concepts of measures based on the model which would assess the directness of the engagements between the user and the interface at each stage of the model. We created operational definitions of the concepts of directness, and derived observable indicators that certain types of indirectness may exist in the interface design. This phase of our research program involved using these concepts as a basis for a methodology of analyzing data collected during usability studies. A usability study was performed on the Military Airspace Management System (MAMS) prototype; four participants' and one user interface expert's data were used for further analysis. DTIC

SIMULATED SUSTAINED FLIGHT OPERATIONS AND PERFORMANCE. PART 1: EFFECTS OF FATIGUE
D. F. Neri, S. A. Shappell, and C. A. DeJohn Jul. 1992 22 p
(AD-A261012) Avail: CASI HC A03/MF A01

Sustained flight operations are likely to produce fatigue and performance decrement in aviators. We assessed changes in cognitive performance using a work/rest schedule modeled on successive long-range attack missions. Twelve subjects performed several subtests of the Unified Tri-Service Cognitive Performance Assessment Battery an the Walter Reed Performance Assessment Battery 18 times during a simulated sustained operation. The scenario consisted of a 9-hr planning session followed by a 4-hr rest period and a 14-hr daytime mission. After 6 hr of rest, subjects repeated this schedule with a nighttime mission. For two spatial tests, subjects showed linear increases in response rate and one of its components, error rate. Subjects appeared to change strategy as the study progressed, possibly exchanging a higher failure rate for a savings in time. Any tendency to take chances when fatigued may serious implications for aircrew in sustained operations. DTIC

MODELING OF A FULL VISION SYSTEM USING COMBINED VISUAL/HAPTIC SEARCH FOR REMOTE OBJECT IDENTIFICATION M.S. Thesis
David L. Klein Dec. 1992 65 p
(AD-A260977) Avail: CASI HC A04/MF A01

It is proposed that a hybrid sensory feedback system comprising a visual peripheral component together with a haptic component corresponding to that of visual foveal information, is equivalent to that of full visual sensory feedback. Such a system is constructed and the ability of subjects to perceive objects using it is investigated by observing and classifying their search strategy. Although the provision of a peripheral component provides advantages over a purely haptic system, it is concluded that subjects rely heavily on the haptic data, and the resulting hybrid system is not equivalent to full vision. MEMBRANE TECHNOLOGY: A SEARCH FOR MEMBRANES FOR SUBMARINE ATMOSPHERE CONTROL
S. P. Roe 1992 12 p
(AD-A260581; MRL-GD-0040; DODA-AR-006-899) Avail: CASI HC A03/MF A01

This overview of membrane technology covers the development of devices which can separate carbon dioxide from air and many other feed gases and the factors influencing selection and performance of such systems. Of the polymeric materials investigated for the separation of carbon dioxide from air, dimethyl silicone (25 percent) rubber membranes exhibit the highest permeability for carbon dioxide, while cellulose acetate exhibits the highest separation factor (10.9) of carbon dioxide to oxygen. However, an immobilized film membrane (IFM) device constructed of a cellulose acetate membrane impregnated with a cesium bicarbonate and sodium arsenite solution exhibits the highest recorded separation factor of 4100. Since a membrane must exhibit a separation factor of at least 100 in order to be effective in any life support system, the IFM method is at present the only approach worthy of further research and development in support of submarine atmosphere control. ARCHITECTURE OF AUTONOMOUS SYSTEMS Final Report
Piyush Dikshit, Katia Guimaraes, Maya Ramamurthy, Ashok Agrawala, and Ronald L. Larsen Nov. 1986 56 p
(Contract NCC2-414)
(NASA-CR-192974; NAS 1.26:192974; SDAG-TN-86-01) Avail: CASI HC A04/MF A01

Automation of Space Station functions and activities, particularly those involving robotic capabilities with interactive or supervisory human control, is a complex, multi-disciplinary systems design problem. A wide variety of applications using autonomous control can be found in the literature, but none of them seem to address the problem in general. All of them are designed with a specific application in mind. In this report, an abstract model is described which unifies the key concepts underlying the design of automated systems such as those studied by the aerospace contractors. The model has been kept as general as possible. The attempt is to capture all the key components of autonomous systems. With a little effort, it should be possible to map the functions of any specific autonomous system application to the model presented here. Author (revised)

INTEGRATED OXYGEN RECOVERY SYSTEM Technical Progress Report No. 2, 9 Mar. - 7 May 1993
M. Gene Lee and Ronald J. Davenport 7 May 1993 22 p
(Contract NAS8-39843)

(NASA-CR-192982; NAS 1.26:192982; TR-1619-1-2) Avail: CASI HC A03/MF A01

Life Systems has conceptualized an innovative Integrated Oxygen Recovery System (IORS) applicable to advanced mission air revitalization. The IORS provides the capability to electrochemically generate metabolic oxygen (O2) and recover O2 from the space habitat atmosphere via a carbon dioxide (CO2) reduction process within a single assembly. To achieve this capability, the IORS utilizes a Solid Metal Cathode (SMC) water electrolysis unit that simultaneously serves as the Sabatier CO2 reduction reactor. The IORS enables two major life support systems currently baselined in closed loop air revitalization systems to be combined into one smaller, less complex system. This concept reduces fluidic and electrical interface requirements and eliminates a hydrogen (H2) interface. Life Systems is performing an evaluation of the IORS process directed at demonstrating performance and quantifying key physical characteristics including power, weight, and volume. The results of the checkout, shakedown, and initial parametric tests are summarized. Author (revised)

AUTOMATION AND ROBOTICS HUMAN PERFORMANCE Annual Report, FY 1989
Robert W. Mah 17 Jan. 1990 135 p
(NASA-CR-193049; NAS 1.26:193049) Avail: CASI HC A07/MF A02

The scope of this report is limited to the following: (1) assessing the feasibility of the assumptions for crew productivity during the intra-vehicular activities and extra-vehicular activities; (2) estimating the appropriate level of automation and robotics to accomplish balanced man-machine, cost-effective operations in space; (3) identifying areas where conceptually different approaches to the use of people and machines can leverage the benefits of the scenarios; and (4) recommending modifications to scenarios or developing new scenarios that will improve the expected benefits. The FY89 special assessments are grouped into the five categories shown in the report. The high level system analyses for Automation & Robotics (A&R) and Human Performance (HP) were performed under the Case Studies Technology Assessment category, whereas the detailed analyses for the critical systems and high leverage development areas were performed under the appropriate operations categories (In-Space Vehicle Operations or Planetary Surface Operations). The analysis activities planned for the Science Operations technology areas were deferred to FY90 studies. The remaining activities such as analytic tool development, graphics/video demonstrations and intelligent communicating systems software architecture were performed under the Simulation & Validations category. COMBINED STRENGTH AND ENDURANCE TRAINING: FUNCTIONAL AND MORPHOLOGICAL ADAPTATIONS TO TEN WEEKS OF TRAINING Final Report, May - Sep. 1991
J. McCarthy, P. Griffith, W. K. Prusaczyk, H. W. Goforth, Jr., and A. Vailas 29 Sep. 1992 20 p
(AD-A261059; NHRC-92-26) Avail: CASI HC A03/MF A01

The literature suggests that muscular strength development can be inhibited when endurance and strength training programs are combined. The purpose of this study was to examine the effects of strength and endurance training programs, individually and in combination, on performance changes and associated muscle adaptations. Sedentary males (n=30) were randomly assigned to one of three training groups: strength-only (STR), endurance-only (END), or combined strength and endurance (COM). Subjects trained three days per week for ten weeks. Strength training consisted of select upper and lower body resistance exercises (three maximal effort sets, five to seven repetitions per set). Endurance training consisted of continuous cycling for 50 min at 70% heart rate reserve (HRR). Subjects in COM engaged in both the strength and endurance training programs on the same day. Anthropometric characteristics, strength, and peak oxygen uptake (cycling) were measured; biopsies were taken from the vastus lateralis muscle; and computed tomography (CT) scans were performed on mid-thigh before and after ten weeks of training. Groups STR and COM showed significant (p less than 0.05) increases in: one-repetition maximum squat (23%, 22%) and bench press (18%, 18%); vertical jump (6%, 9%); lean body weight (3%, 5%); mid-thigh girth (3%, 4%); fast twitch (FT) muscle fiber area (24%, 28%); mean muscle fiber area (21%, 23%); thigh extensor (12%, 14%) and flexor (7%, 6%) areas. All groups exhibited significant increases in peak oxygen uptake following training END (18%), COM (16%), and STR (9%). These results suggest that combining strength and endurance training programs can produce significant concurrent gains in muscular strength and power, muscle hypertrophy, and peak oxygen uptake. INTERPUPILLARY AND VERTEX DISTANCE EFFECTS ON FIELD-OF-VIEW AND ACUITY WITH ANVIS Final Report
James M. King and Stephen E. Morse Jan. 1993 44 p
(DA Proj. 3M1-62787-A-879)
(AD-A261259; USAARL-93-9) Avail: CASI HC A03/MF A01

Third generation Aviation Night Vision Imaging Systems (ANVIS) employ vertical, tilt, interpupillary distance, vertex distance, and focus adjustments. ANVIS field-of-view is nominally 40 degrees but can be limited by adjustments. Interpupillary distance effects on ANVIS field-of-view have been computed, but seldom measured. There have been reports of acuity loss at the periphery of ANVIS fields-of-view. Fields-of-view were measured in 10 subjects, acuities in 8. ANVIS were used with a 10-foot working distance. Acuities were Assessed using Bailey-Lovie charts. At the 18 mm vertex distance, binocular and monocular fields-of-view decreased with decentration. At the 32 mm vertex distance, binocular and monocular fields-of-view were reduced at optimal interpupillary distance, and decreased with increasing decentration. The total horizontal field-of-view at 32 mm vertex distance was increased by increasing decentration, offsetting the reduction caused by increased vertex distance. Acuity was relatively insensitive to changes in vertex distance and interpupillary distance, but was substantially reduced in the periphery of the field-of-view, and under low contrast. DTIC

ANTHROPOMETRY OF THE FOOT AND LOWER LEG OF U.S. ARMY SOLDIERS: FORT JACKSON, SC Final Report, Jun. 1985 - Dec. 1988
Kenneth R. Parham, Claire C. Gordon, and Carolyn K. Bensel Sep. 1992 358 p
(AD-A261405; NATICK/TR-92/028) Avail: CASI HC A16/MF A03

In 1985, a fit test for a leather combat boot, which was recently adopted by the US Army, was conducted at Fort Jackson, South Carolina by the US Army Natick Research, Development and Engineering Center. In conjunction with the fit test, a series of 33 anthropometric measurements of the foot and lower leg (including stature and weight) was obtained on 867 male and female soldiers. This report presents statistical information for those data on the full male sample (n=293) and on a female subsample (n=491), which has been reconfigured to represent more closely the demographic composition of the current US Army female population. In addition to measurement descriptions and summary statistics for each variable by gender, bivariate and multivariate relationships in the data are also presented. This includes bivariate tables, correlation coefficients, and both simple and multiple regression equations. These data represent the most comprehensive anthropometric information on the foot collected to date. As such, the statistical information presented in this report should be of value to scientists and to developers of both military and civilian footwear. DTIC

This report summarizes the results of the Planetary Biology and Molecular Ecology's summer 1991 program, which was held at the Marine Biological Laboratory in Woods Hole, Massachusetts. The purpose of the interdisciplinary PBME program is to integrate, via lectures and laboratory work, the contributions of university and NASA scientists and student interns. The goals of the 1991 program were to examine several aspects of the biogeochemistry of the nitrogen cycle and to teach the application of modern methods of molecular genetics to field studies of organisms. Descriptions of the laboratory projects and protocols and abstracts and references of the lectures are presented. Author (revised)

Knowledge of the three-dimensional world is essential for many guidance and navigation applications. A sequence of images from an electro-optical sensor can be processed using optical flow algorithms to provide a sparse set of ranges as a function of azimuth and elevation. A natural way to enhance the range map is by interpolation. However, this should be undertaken with care since interpolation assumes continuity of range. The range is continuous in certain parts of the image and can jump at object boundaries. In such situations, the ability to detect homogeneous object regions by scene segmentation can be used to determine regions in the range map that can be enhanced by interpolation. The use of scalar features derived from the spatial gray-level dependence matrix for texture segmentation is explored. Thresholding of histograms of scalar texture features is done for several images to select scalar features which result in a meaningful segmentation of the images. Next, the selected scalar features are used with a neural net to automate the segmentation procedure. Back-propagation is used to train the feed forward neural network. The generalization of the network approach to subsequent images in the sequence is examined. It is shown that the use of multiple scalar features as input to the neural network result in a superior segmentation when compared with a single scalar feature. It is also shown that the scalar features, which are not useful individually, result in a good segmentation when used together. The methodology is applied to both indoor and outdoor images. Author

This document is the proceedings from a Space and Earth Science Data Compression Workshop, which was held on March 27, 1992, at the Snowbird Conference Center in Snowbird, Utah. This workshop was held in conjunction with the 1992 Data Compression Conference (DCC '92), which was held at the same location, March 24-26, 1992. The workshop explored opportunities for data compression to enhance the collection and analysis of space and Earth science data. The workshop consisted of eleven papers presented in four sessions. These papers describe research that is integrated into, or has the potential of being integrated into, a particular space and/or Earth science data information system. Presenters were encouraged to take into account the scientists's data requirements, and the constraints imposed by the data collection, transmission, distribution, and archival system. For individual titles, see N93-25922 through N93-25932.

ADJUSTABLE LOSSLESS IMAGE COMPRESSION BASED ON A NATURAL SPLITTING OF AN IMAGE INTO DRAWING, SHADING, AND FINE-GRAINED COMPONENTS **c82**
Dmitry A. Novik and James C. Tilton (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.) *In its* The Space and Earth Science Data Compression Workshop 1993 p 17-25 (For primary document see N93-25921 09-59)
Avail: CASI HC A02/MF A02

The compression, or efficient coding, of single band or multispectral still images is becoming an increasingly important topic. While lossy compression approaches can produce reconstructions that are visually close to the original, many scientific and engineering applications require exact (lossless) reconstructions. However, the most popular and efficient lossless compression techniques do not fully exploit the two-dimensional structural links existing in the image data. We describe here a general approach to lossless data compression that effectively exploits two-dimensional structural links of any length. After describing in detail two main variants on this scheme, we discuss experimental results. Author

The process of contourization is presented which converts a raster image into a set of plateaux or contours. These contours can be grouped into a hierarchical structure, defining total spatial inclusion, called a contour tree. A contour coder has been developed which fully describes these contours in a compact and efficient manner and is the basis for an image compression method. Simplification of the contour tree has been undertaken by merging contour tree nodes thus lowering the contour tree's entropy. This can be exploited by the contour coder to increase the image compression ratio. By applying general and simple rules derived from physiological experiments on the human vision system, lossy image compression can be achieved which minimizes noticeable artifacts in the simplified image. Data compression is essential to current low-earth-orbit spectral sensors with global coverage, e.g., meteorological sensors. Such sensors routinely produce in excess of 30 Gb of data per orbit (over 4 Mb/s for about 110 min) while typically limited to less than 10 Gb of downlink capacity per orbit (15 minutes at 10 Mb/s). Astro-Space Division develops spaceborne compression systems for compression ratios from as little as three to as much as twenty-to-one for high-fidelity reconstructions. Current hardware production and development at Astro-Space Division focuses on discrete cosine transform (DCT) systems implemented with the GE PFFT chip, a 32x32 2D-DCT engine. Spectral relations in the data are exploited through block mean extraction followed by orthonormal transformation. The transformation produces blocks with spatial correlation that are suitable for further compression with any block-oriented spatial compression system, e.g., Astro-Space Division's Laplacian modeler and analytic encoder of DCT coefficients. It is recognized that mean square error (MSE) is not a sufficient criterion for determining the acceptability of an image reconstructed from data that has been compressed and decompressed using an encoding algorithm. In the case of Synthetic Aperture Radar (SAR) data, it is also deemed to be insufficient to display the reconstructed image (and perhaps error image) alongside the original and make a (subjective) judgment as to the quality of the reconstructed data. In this paper we suggest a number of additional evaluation criteria which we feel should be included as evaluation metrics in SAR data encoding experiments. These criteria have been specifically chosen to provide a means of ensuring that the important information in the SAR data is preserved. The paper also presents the results of an investigation into the effects of coding on SAR data fidelity when the coding is applied in (1) the signal data domain, and (2) the image domain. An analysis of the results highlights the shortcomings of the MSE criterion, and shows which of the suggested additional criterion have been found to be most important. Author

FRACTAL IMAGE COMPRESSION: A RESOLUTION INDEPENDENT REPRESENTATION FOR IMAGERY **c82**
Alan D. Sloan *In* NASA. Goddard Space Flight Center, The Space and Earth Science Data Compression Workshop 1993 p 73-79 (For primary document see N93-25921 09-59)
Avail: CASI HC A02/MF A02

A deterministic fractal is an image which has low information content and no inherent scale. Because of their low information content, deterministic fractals can be described with small data sets. They can be displayed at high resolution since they are not bound by an inherent scale. A remarkable consequence follows. Fractal images can be encoded at very high compression ratios. This fern, for example is encoded in less than 50 bytes and yet can be displayed at resolutions with increasing levels of detail appearing. The Fractal Transform was discovered in 1988 by Michael F. Barnsley. It is the basis for a new image compression scheme which was initially developed by myself and Michael Barnsley at Iterated Systems. The Fractal Transform effectively solves the problem of finding a fractal which approximates a digital 'real world image'. Author

Data compression has been proposed for several flight missions as a means of either reducing on board mass data storage, increasing science data return through a bandwidth constrained channel, reducing TDRSS access time, or easing ground archival mass storage requirement. Several issues arise with the implementation of this technology. These include the requirement of a clean channel, onboard smoothing buffer, onboard processing hardware and on the algorithm itself, the adaptability to scene changes and maybe even versatility to the various mission types. This paper gives an overview of an ongoing effort being performed at Goddard Space Flight Center for implementing a lossless data compression scheme for space flight. We will provide analysis results on several data systems issues, the performance of the selected lossless compression scheme, the status of the hardware processor and current development plan. How do you store enough of the key data sets, from a total of 120 gigabytes of data collected for a scientific experiment, on a collection of CD-ROM's, small enough to distribute to a broad scientific community? In such an application where information loss in unacceptable, lossless compression algorithms are the only choice. Although lossy compression algorithms can provide an order of magnitude improvement in compression ratios over lossless algorithms the information that is lost is often part of the key scientific precision of the data. Therefore, lossless compression algorithms are and will continue to be extremely important in minimizing archiving storage requirements and distribution of large earth and space (ESS) data sets while preserving the essential scientific precision of the data. Current plans indicate that there will be a large number of life science experiments carried out during the thirty year-long mission of the Biological Flight Research Laboratory (BFRL) on board Space Station Freedom (SSF). Non-human life science experiments will be performed in the BFRL. Two distinct types of activities have already been identified for this facility: (1) collect, store, distribute, analyze and manage engineering and science data from the Habitats, Glovebox and Centrifuge, (2) perform a broad range of remote science activities in the Glovebox and Habitat chambers in conjunction with the remotely located principal investigator (PI). These activities require extensive video coverage, viewing and/or recording and distribution to video displays on board SSF and to the ground. This paper concentrates mainly on the second type of activity. Each of the two BFRL habitat racks are designed to be configurable for either six rodent habitats per rack, four plant habitats per rack, or a combination of the above. Two video cameras will be installed in each habitat with a spare attachment for a third camera when needed. Therefore, a video system that can accommodate up to 12-18 camera inputs per habitat rack must be considered. Author

Astronomical images have some rather unusual characteristics that make many existing image compression techniques either ineffective or inapplicable. A typical image consists of a nearly flat background sprinkled with point sources and occasional extended sources. The images are often noisy, so that lossless compression does not work very well; furthermore, the images are usually subjected to stringent quantitative analysis, so any lossy compression method must be proven not to discard useful information, but must instead discard only the noise. Finally, the images can be extremely large. For example, the Space Telescope Science Institute has digitized photographic plates covering the entire sky, generating 1500 images each having 14000 x 14000 16-bit pixels. Several astronomical groups are now constructing cameras with mosaics of large CCD's (each 2048 x 2048 or larger); these instruments will be used in projects that generate data at a rate exceeding 100 MBytes every 5 minutes for many years. An effective technique for image compression may be based on the H-transform (Fritze et al. 1977). The method that we have developed can be used for either lossless or lossy compression. The digitized sky survey images can be compressed by at least a factor of 10 with no noticeable losses in the astrometric and photometric properties of the compressed images. The method has been designed to be computationally efficient: compression or decompression of a 512 x 512 image requires only 4 seconds on a Sun SPARCstation 1. The algorithm uses only integer arithmetic, so it is completely reversible in its lossless mode, and it could easily be implemented in hardware for space applications. Author

MULTI-RATE, REAL TIME IMAGE COMPRESSION FOR IMAGES DOMINATED BY POINT SOURCES **c82**
A. Kris Huber, Scott E. Budge, and Richard W. Harris *In* NASA. Goddard Space Flight Center, The Space and Earth Science Data Compression Workshop 1993 p 125-135 Sponsored by Space Dynamics Lab. (For primary document see N93-25921 09-59)
Avail: CASI HC A03/MF A02

An image compression system recently developed for compression of digital images dominated by point sources is presented. Encoding consists of minimum-mean removal, vector quantization, adaptive threshold truncation, and modified Huffman encoding. Simulations are presented showing that the peaks corresponding to point sources can be transmitted losslessly for low signal-to-noise ratios (SNR) and high point source densities while maintaining a reduced output bit rate. Encoding and decoding hardware has been built and tested which processes 552,960 12-bit pixels per second at compression rates of 10:1 and 4:1. Simulation results are presented for the 10:1 case only. Author

ROBO-LINE STORAGE: LOW LATENCY, HIGH CAPACITY STORAGE SYSTEMS OVER GEOGRAPHICALLY DISTRIBUTED NETWORKS
Randy H. Katz, Thomas E. Anderson, John K. Ousterhout, and David A. Patterson Sep. 1991 27 p
(Grant NAG2-591)
(NASA-CR-192910; NAS 1.26:192910; UCB/CSD-91/651) Avail: CASI HC A03/MF A01

Rapid advances in high performance computing are making possible more complete and accurate computer-based modeling of complex physical phenomena, such as weather front interactions, dynamics of chemical reactions, numerical aerodynamic analysis of airframes, and ocean-land-atmosphere interactions. Many of these 'grand challenge' applications are as demanding of the underlying storage system, in terms of their capacity and bandwidth requirements, as they are on the computational power of the processor. A global view of the Earth's ocean chlorophyll and land vegetation requires over 2 terabytes of raw satellite image data. In this paper, we describe our planned research program in high capacity, high bandwidth storage systems. The project has four overall goals. First, we will examine new methods for high capacity storage systems, made possible by low cost, small form factor magnetic and optical tape systems. Second, access to the storage system will be low latency and high bandwidth. To achieve this, we must interleave data transfer at all levels of the storage system, including devices, controllers, servers, and communications links. Latency will be reduced by extensive caching throughout the storage hierarchy. Third, we will provide effective management of a storage hierarchy, extending the techniques already developed for the Log Structured File System. Finally, we will construct a prototype high capacity file server, suitable for use on the National Research and Education Network (NREN). Such research must be a Cornerstone of any coherent program in high performance computing and communications.

RAID-2: DESIGN AND IMPLEMENTATION OF A LARGE SCALE DISK ARRAY CONTROLLER
R. H. Katz, P. M. Chen, A. L. Drapeau, E. K. Lee, K. Lutz, E. L. Miller, S. Seshan, and D. A. Patterson 6 Oct. 1992 18 p
(Grant NAG2-591)
(NASA-CR-192911; NAS 1.26:192911; UCB/CSD-92/705) Avail: CASI HC A03/MF A01

We describe the implementation of a large scale disk array controller and subsystem incorporating over 100 high performance 3.5 inch disk drives. It is designed to provide 40 MB/s sustained performance and 40 GB capacity in three 19 inch racks. The array controller forms an integral part of a file server that attaches to a Gb/s local area network. The controller implements a high bandwidth interconnect between an interleaved memory, an XOR calculation engine, the network interface (HIPPI), and the disk interfaces (SCSI). The system is now functionally operational, and we are tuning its performance. We review the design decisions, history, and lessons learned from this three year university implementation effort to construct a truly large scale system assembly. Author (revised)

STRIPED TAPE ARRAYS
Ann L. Drapeau and Randy H. Katz 1992 10 p
(Grant NAG2-591)
(NASA-CR-192914; NAS 1.26:192914) Avail: CASI HC A02/MF A01

A growing number of applications require high capacity, high throughput tertiary storage systems. How data striping ideas apply to arrays of magnetic tape drives is investigated. Data striping increases throughput and reduces response time for large accesses to a storage system. Striped magnetic tape systems are particularly appealing because many inexpensive magnetic tape drives have low bandwidth; striping may offer dramatic performance improvements for these systems. There are several important issues in designing striped tape systems: the choice of tape drives and robots, whether to stripe within or between robots, and the choice of the best scheme for distributing data on cartridges. One of the most troublesome problems in striped tape arrays is the synchronization of transfers across tape drives. Another issue is how improved devices will affect the desirability of striping in the future. The results of simulations comparing the performance of striped tape systems to non-striped systems are presented.

VERY HIGH-SPEED ARITHMETIC PROCESSORS (THE GAUSS MACHINE) Final Report
Fred J. Taylor 29 Oct. 1992 173 p
(Contract DAAL03-89-K-0147)
(AD-A260693; ARO-26735.1-EL) Avail: CASI HC A08/MF A02

Our VHSAP ARO study has lead to a number of accomplishments including an original VLSI processor and a system with a high residue number system (RNS) content called the Gauss Machine. The Gauss machine is a SIMD systolic array architecture which takes advantage of the Galois-enhanced quadratic residue number system (GEQRNS) to form reduced complexity arithmetic elements. The Gauss machine is targeted at front-end signal and image processing applications. With a 2x2 array of GEQRNS multiplier accumulators operating at 10 MHz, the Gauss machine can achieve a peak equivalent throughput of 320 million operations per second when performing complex arithmetic. The Gauss machine is designed for a broader, more general class of problems other than RNS based systems which have been constructed: the Gauss machine may be used to accelerate computations which involve or may be expressed as matrix-matrix (level 3), matrix-vector (level 2), or vector-vector (level 1) operations. This paper describes the implementation of the Gauss machine and how it may be used to accelerate signal processing operations. DTIC

The central component of standard approaches to compile-time program analysis is an abstract domain for approximating program values. Importantly, the domain must be chosen so that an iterative fixed point computation over the domain terminates. This requirement represents a substantial restriction on the accuracy of the analysis. Furthermore, it leads to complex and often chaotic behavior. We present an alternative approach to program analysis, called set based analysis. A key feature of set based analysis is that reasoning about a program's run-time behavior is reduced to reasoning about constraints on sets of program values. Set based analysis incorporates just a single notion of approximation: all dependencies arising from the treatment of program variables are ignored. The main advantage of set based analysis is improved accuracy, due to the absence of an abstract domain. Additionally, the use of a very simple and uniform notion of approximation leads to program analysis that is easier to understand and less sensitive to minor program modifications. DTIC

COMPUTER-AIDED DESIGN PACKAGE FOR DESIGNERS OF DIGITAL OPTICAL COMPUTERS
Miles Murdocca Feb. 1993 4 p
(Contract N00014-90-J-4018)
(AD-A260757) Avail: CASI HC A01/MF A01

This report covers progress for the period 10/1/92 - 12/31/93 on a jointly sponsored ONR/AFOSR grant to Rutgers University which supports research into the architecture and design of digital optical computers. During this reporting period Murdocca developed the notion of a reconfigurable logic/interconnection component (RELIC) as part of an investigation into the architectural implications of reconfiguration optical interconnects. Prof. Thomas Stone made progress on the study of hybrid micro-macro optics for optical interconnection, achromatic optical interconnects, and the use of birefringent materials for optical interconnection. In addition, our experimental facilities have improved and related work has progressed at the Photonics Center at Rome Laboratory where we have found a good opportunity for technology transfer. DTIC

AN INVESTIGATION OF MEMORY LATENCY REDUCTION USING AN ADDRESS PREDICTION BUFFER M.S. Thesis
Arthur B. Billingsley Dec. 1992 39 p
(AD-A261010) Avail: CASI HC A03/MF A01

Developing memory systems to support high-speed processors is a major challenge to computer architects. Cache memories can improve system performance but the latency of main memory remains a major penalty for a cache-miss. A novel approach to improve system performance is the use of a memory prediction buffer. The memory prediction buffer (MPB) is inserted between the cache and main memory. The MPB predicts the next cache-miss address and pre-fetches the data. The use of an MPB in a computer system is shown to decrease main-memory latency and increase system performance . DTIC

THE DESIGN AND IMPLEMENTATION OF A READ PREDICTION BUFFER M.S. Thesis
Gary J. Nowicki Dec. 1992 204 p
(AD-A260902) Avail: CASI HC A10/MF A03

Cache memories, which are the level of memory between the central processing unit (CPU) and the main memory, hold small amounts of data and instructions and allow the CPU to access the contents in them very quickly. This significantly reduces the read access time for the CPU if the

required information is available in the cache. However, caches are small and can only hold the most commonly used data and instructions required by the CPU. When information requested does not appear in the cache, a 'cache miss' occurs and the CPU must fetch the required data from the main memory. The Read Prediction Buffer reduces this time-costly read access by attempting to predict the possible miss address, and pre-fetch the read data. DTIC

HIGH PERFORMANCE COMPUTING AND COMMUNICATIONS PANEL REPORT
Dec. 1992 12 p
Avail: CASI HC A03/MF A01

In FY-92, a presidential initiative was launched, aimed at securing U.S. preeminence in high performance computing and related communication technologies. The initiative, entitled High Performance Computing and Communications (HPCC), is one of five initiatives coordinated by the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET) process. Nine federal agencies are currently involved, with the Defense Advanced Research Project Agency, the Department of Energy, the National Aeronautics and Space Administration, and the National Science Foundation providing the principal program funding and direction. Lesser but important roles are being played by the National Oceanic and Atmospheric Administration, the National Institute of Standards and Technology, the Environmental Protection Agency, the Department of Education, and the National Institutes of Health. The stated goal of the initiative is threefold: extend U.S. technological leadership in high performance computing and computer communications; provide wide dissemination and application of the technologies; and spur gains in U.S. productivity and industrial competitiveness, all within the context of the mission needs of federal agencies. The strategy for accomplishing the goals and the program components are highlighted in the report 'Grand Challenges: High Performance Computing and Communications,' published as a supplement to the fiscal year 1992 and 1993 budgets. HUMAN COMPUTER INTERFACE STYLE GUIDE, VERSION 2.0 Final Report
30 Sep. 1992 565 p Supersedes DoD HCI Style Guide V1.0, AD-A253475
(AD-A261280) Avail: CASI HC A24/MF A04

The purpose of this Style Guide is to provide a common framework for HCI design and implementation. Through this framework, the long-term functional goals, objectives, and requirements of the HCI will be defined and documented. Interface implementation options will be standardized, enabling all DoD applications to appear and operate in a reasonably consistent manner. DTIC

ADVANCED TECHNOLOGY FOR PORTABLE PERSONAL VISUALIZATION Progress Report, Jul. 1992 - Jan. 1993
Frederick P. Brooks, Jr. and Henry Fuchs Jan. 1993 61 p
(Contract DAEA18-90-C-0044)
(AD-A261294) Avail: CASI HC A04/MF A01

Despite the recent avalanche of publicity on virtual reality, the state of the art in head-mounted displays (HMD) is still at the almost-works stage. Although extravagant claims are made almost daily on television and in the popular press, there is very little that can be usefully accomplished today with virtual reality technologies. We at UNC have been working since the early 1970s on aspects of these technologies and have been advancing the state of the art by a driving problem approach; we let the needs of selected applications stimulate the direction of the technological developments and then test new results by observing their impact on solving the original application. We are working on three application areas: molecular modeling, 3D medical imaging, and modeling of architectural interiors. We have developed complete systems that include the head-mounted display device, the display generation hardware, and a head and hand tracker. We have access to a force-feedback ARM that is owned by the GRIP project. DTIC

CONSIDERATIONS FOR SPACE AND NAVAL AVIATION APPLICATIONS OF FERROELECTRIC MEMORY M.S. Thesis
Theodore A. Vetter Dec. 1992 77 p
(AD-A261300) Avail: CASI HC A05/MF A01

The purpose of this thesis is to introduce the reader to Ferroelectric memory and discuss considerations for possible space and Naval aviation applications. Ferroelectric memory's characteristics and basic mechanism are discussed. A broad spectrum of existing computer memory types are presented for comparison. The memory requirements of Space Shuttle, Landsat, Intelsat VI and Hubble Space Telescope as well as the Navy E-2 Hawkeye and EA-6B Prowler aircraft are given as possible examples of space and Naval aviation applications of ferroelectric memory. PROCEEDINGS OF THE COMPLEX SYSTEMS ENGINEERING SYNTHESIS AND ASSESSMENT TECHNOLOGY WORKSHOP
Cuong M. Nguyen 24 Jul. 1992 618 p Workshop held in Silver Spring, MD, 20-24 Jul. 1992
(AD-A261404; NSWCDD/MP-92/304) Avail: CASI HC A99/MF A06

The emphasis of CSESAW'92 is on exploring system-level design synthesis and assessment capabilities for mission critical computer systems. These capabilities will facilitate the development of such systems from informal system requirements, through the design phase prototyping, and into implementation and post deployment. Component products produced by these capabilities are specifications that subenvironments will receive. The focus of this workshop is the development and integration of these multiple technologies and the exploration of the creation of a system-level engineering discipline with support technologies to provide potential high payoff solutions to the difficult problems encountered by designers, developers, and maintainers of large, complex, real-time systems. The emphasis is on resolving system-level technology issues that cut across component boundaries, such as those associated with system behavior requirements of real time, fault tolerance, and security. DIRECTORY OF US GOVERNMENT SOFTWARE FOR MAINFRAMES AND MICROCOMPUTERS, 1993 Annual Report
Jan. 1993 174 p Supersedes PB92-100106
(PB93-111565; ISBN-0-934213-37-2) Avail: CASI HC A08/MF A02

The directory contains descriptions of some 550 mainframe and microcomputer programs made available from more than 100 Federal agencies, or their contractors, since 1984. The major government agencies whose computer programs are included in the directory are the Departments of Defense, Energy, and Health and Human Services; the Environmental Protection Agency; the Food and Drug Administration; the National Library of Medicine; and the National Bureau of Standards. The directory is an essential reference tool for users who wish to tap the wealth of U.S. Government software. The annual listing is the only complete record of government-produced computer programs. GEOMETRIC MODELING FOR COMPUTER AIDED DESIGN Progress Report, period ending 1 Jan. 1993
James L. Schwing Apr. 1993 152 p
(Contract NCC1-99)
(NASA-CR-192891; NAS 1.26:192891) Avail: CASI HC A08/MF A02

Over the past several years, it has been the primary goal of this grant to design and implement software to be used in the conceptual design of aerospace vehicles. The work carried out under this grant was performed jointly with members of the Vehicle Analysis Branch (VAB) of NASA LaRC, Computer Sciences Corp., and Vigyan Corp. This has resulted in the development of several packages and design studies. Primary among these are the interactive geometric modeling tool, the Solid Modeling Aerospace Research Tool (smart), and the integration and execution tools provided by the Environment for Application Software Integration and Execution (EASIE). In addition, it is the purpose of the personnel of this grant to provide consultation in the areas of structural design, algorithm development, and software development and implementation, particularly in the areas of computer aided design, geometric surface representation, and parallel algorithms. RAPID EXPLORATION OF CURVILINEAR GRIDS USING DIRECT VOLUME RENDERING
Allen VanGelder and Jane Wilhelms 16 Mar. 1993 14 p
(Contract NCC2-717)
(NASA-CR-192765; NAS 1.26:192765; UCSC-CRL-93-02) Avail: CASI HC A03/MF A01

Fast techniques for direct volume rendering over curvilinear grids of hexahedral cells are developed. This type of 3D grid is common in computational fluid dynamics and finite element analysis. Four new projection methods are presented and compared with each other and with previous methods for tetrahedral grids and rectilinear grids. All four methods use polygon-rendering hardware for speed. A simplified algorithm for visibility ordering, which is based on a combination of breadth-first and depth-first searches, is described. A new multi-pass blending method is described that reduces visual artifacts that are introduced by linear interpolation in hardware where exponential interpolation is needed. Multi-pass blending is of equal interest to hardware-oriented projection methods used on rectilinear grids. Visualization tools that permit rapid data banding and cycling through transfer functions, as well as region restrictions, are described. Author

FEDERAL COMMUNICATIONS COMMISSION (FCC) TRANSPONDER LOADING DATA CONVERSION SOFTWARE. USER'S GUIDE AND SOFTWARE MAINTENANCE MANUAL, VERSION 1.2
Paul G. Mallasch Jan. 1993 82 p
(Contract NAS3-25776; RTOP 144-10-10)
(NASA-CR-191067; E-7570; NAS 1.26:191067) Avail: CASI HC A05/MF A01

This volume contains the complete software system documentation for the Federal Communications Commission (FCC) Transponder Loading Data Conversion Software (FIX-FCC). This software was written to facilitate the formatting and conversion of FCC Transponder Occupancy (Loading) Data before it is loaded into the NASA Geosynchronous Satellite Orbital Statistics Database System (GSOSTATS). The information that FCC supplies NASA is in report form and must be converted into a form readable by the database management software used in the GSOSTATS application. Both the User's Guide and Software Maintenance Manual are contained in this document. This volume of documentation passed an independent quality assurance review and certification by the Product Assurance and Security Office of the Planning Research Corporation (PRC). The manuals were reviewed for format, content, and readability. The Software Management and Assurance Program (SMAP) life cycle and documentation standards were used in the development of this document. Accordingly, these standards were used in the review. Refer to the System/Software Test/Product Assurance Report for the Geosynchronous Satellite Orbital Statistics Database System (GSOSTATS) for additional information. Author

A COMPARISON USING APPL AND PVM FOR A PARALLEL IMPLEMENTATION OF AN UNSTRUCTURED GRID GENERATION PROGRAM
Trey Arthur and Michael J. Bockelie Jan. 1993 16 p
(Contract NAS1-19038; RTOP 505-90-53-02)
(NASA-CR-191425; NAS 1.26:191425; TAO-60322) Avail: CASI HC A03/MF A01

Efforts to parallelize the VGRIDSG unstructured surface grid generation program are described. The inherent parallel nature of the grid generation algorithm used in VGRIDSG was exploited on a cluster of Silicon Graphics IRIS 4D workstations using the message passing libraries Application Portable Parallel Library (APPL) and Parallel Virtual Machine (PVM). Comparisons of speed up are presented for generating the surface grid of a unit cube and a Mach 3.0 High Speed Civil Transport. It was concluded that for this application, both APPL and PVM give approximately the same performance, however, APPL is easier to use. Author (revised)

ON THE ROBUSTNESS OF HERLIHY'S HIERARCHY
Prasad Jayanti Mar. 1993 35 p Sponsored in part by the IBM Endicott Programming Lab. and Siemens Corp.
(Grants NAG2-593; NSF CCR-89-01780; NSF CCR-91-02231)
(NASA-CR-193002; NAS 1.26:193002; CU-TR-93-1332) Avail: CASI HC A03/MF A01

A wait-free hierarchy maps object types to levels in Z(+) U (infinity) and has the following property: if a type T is at level N, and T' is an arbitrary type, then there is a wait-free implementation of an object of type T', for N processes, using only registers and objects of type T. The infinite hierarchy defined by Herlihy is an example of a wait-free hierarchy. A wait-free hierarchy is robust if it has the following property: if T is at level N, and S is a finite set of types belonging to levels N - 1 or lower, then there is no wait-free implementation of an object of type T, for N processes, using any number and any combination of objects belonging to the types in S. Robustness implies that there are no clever ways of combining weak shared objects to obtain stronger ones. Contrary to what many researchers believe, we prove that Herlihy's hierarchy is not robust. We then define some natural variants of Herlihy's hierarchy, which are also infinite wait-free hierarchies. With the exception of one, which is still open, these are not robust either. We conclude with the open question of whether non-trivial robust wait-free hierarchies exist. Author (revised)

AN ANALYSIS OF FILE MIGRATION IN A UNIX SUPERCOMPUTING ENVIRONMENT
Ethan L. Miller and Randy H. Katz Nov. 1992 13 p
(Grant NAG2-591)
(NASA-CR-192908; NAS 1.26:192908; UCB/CSD-92/712) Avail: CASI HC A03/MF A01

The super computer center at the National Center for Atmospheric Research (NCAR) migrates large numbers of files to and from its mass storage system (MSS) because there is insufficient space to store them on the Cray supercomputer's local disks. This paper presents an analysis of file migration data collected over two years. The analysis shows that requests to the MSS are periodic, with one day and one week periods. Read requests to the MSS account for the majority of the periodicity; as write requests are relatively constant over the course of a week. Additionally, reads show a far greater fluctuation than writes over a day and week since reads are driven by human users while writes are machine-driven.

PUTTING TIME INTO PROOF OUTLINES
Fred B. Schneider, Bard Bloom, and Keith Marzullo 10 Mar. 1993 33 p
Sponsored in part by IBM Endicott Programming Lab. and Siemens Corp.
(Contract NAG2-593; N00014-91-J-1219; NSF CCR-87-01103; NSF CCR-90-14363)
(NASA-CR-192978; NAS 1.26:192978; CU-TR-93-1333) Avail: CASI HC A03/MF A01

A logic for reasoning about timing properties of concurrent programs is presented. The logic is based on Hoare-style proof outlines and can handle maximal parallelism as well as certain resource-constrained execution environments. The correctness proof for a mutual exclusion protocol that uses execution timings in a subtle way illustrates the logic in action. A soundness proof using structural operational semantics is outlined in the appendix.

USING A CRAY Y-MP AS AN ARRAY PROCESSOR FOR A RISC WORKSTATION
Hugh LaMaster and Sarah J. Rogallo Nov. 1992 17 p
(RTOP 505-59-00)
(NASA-TM-103961; A-92158; NAS 1.15:103961) Avail: CASI HC A03/MF A01

As microprocessors increase in power, the economics of centralized computing has changed dramatically. At the beginning of the 1980's, mainframes and super computers were often considered to be cost-effective machines for scalar computing. Today, microprocessor-based RISC (reduced-instruction-set computer) systems have displaced many uses of mainframes and supercomputers. Supercomputers are still cost competitive when processing jobs that require both large memory size and high memory bandwidth. One such application is array processing. Certain numerical operations are appropriate to use in a Remote Procedure Call (RPC)-based environment. Matrix multiplication is an example of an operation that can have a sufficient number of arithmetic operations to amortize the cost of an RPC call. An experiment which demonstrates that matrix multiplication can be executed remotely on a large system to speed the execution over that experienced on a workstation is described.
